

STRONG FAILURES OF HIGHER ANALOGS OF HINDMAN'S THEOREM

DAVID FERNÁNDEZ-BRETÓN AND ASSAF RINOT

This paper is dedicated to the memory of András Hajnal (1931–2016)

ABSTRACT. We show that various analogs of Hindman's Theorem fail in a strong sense when one attempts to obtain uncountable monochromatic sets:

Theorem 1. There exists a colouring $c : \mathbb{R} \rightarrow \mathbb{Q}$, such that for every $X \subseteq \mathbb{R}$ with $|X| = |\mathbb{R}|$, and every colour $\gamma \in \mathbb{Q}$, there are two distinct elements x_0, x_1 of X for which $c(x_0 + x_1) = \gamma$. This forms a simultaneous generalization of a theorem of Hindman, Leader and Strauss and a theorem of Galvin and Shelah.

Theorem 2. For every Abelian group G , there exists a colouring $c : G \rightarrow \mathbb{Q}$ such that for every uncountable $X \subseteq G$, and every colour γ , for some large enough integer n , there are pairwise distinct elements x_0, \dots, x_n of X such that $c(x_0 + \dots + x_n) = \gamma$. In addition, it is consistent that the preceding statement remains valid even after enlarging the set of colours from \mathbb{Q} to \mathbb{R} .

Theorem 3. Let \otimes_κ assert that for every Abelian group G of cardinality κ , there exists a colouring $c : G \rightarrow G$ such that for every positive integer n , every $X_0, \dots, X_n \in [G]^\kappa$, and every $\gamma \in G$, there are $x_0 \in X_0, \dots, x_n \in X_n$ such that $c(x_0 + \dots + x_n) = \gamma$. Then \otimes_κ holds for unboundedly many uncountable cardinals κ , and it is consistent that \otimes_κ holds for *all* regular uncountable cardinals κ .

1. INTRODUCTION

In one of its more general forms, Hindman's Theorem (see [14, Corollary 5.9] for the general form; the particular case $G = \mathbb{N}$ was originally proved in [12]) asserts that whenever a commutative cancellative semigroup G is partitioned into two cells (i.e., coloured with two colours), there exists an infinite $X \subseteq G$ such that the set of its *finite sums*

$$\text{FS}(X) := \left\{ \sum_{x \in a} x \mid a \in [X]^{<\omega} \right\}$$

is completely contained in one of the cells of the partition (i.e., $\text{FS}(X)$ is *monochromatic*). The infinite set $X \subseteq G$ constructed in the proof of this theorem is countable, so it is natural to ask whether it is possible to find, given a colouring of an uncountable commutative cancellative semigroup G , a subset $X \subseteq G$ of a given uncountable cardinality such that $\text{FS}(X)$ is monochromatic. This question was answered in the negative in [6], where, given a commutative cancellative semigroup G , a colouring with two colours of G is exhibited such that no uncountable $X \subseteq G$ can have $\text{FS}(X)$ monochromatic. A related result for the particular case of the group \mathbb{R} can be found in [13], where a colouring of \mathbb{R} with two colours is exhibited, satisfying that whenever $X \subseteq \mathbb{R}$ has the same cardinality as \mathbb{R} , then not only is $\text{FS}(X)$ not monochromatic, but even $\text{FS}_2(X) := \{x + y \mid x, y \in X \text{ distinct}\}$ is not monochromatic. In particular, assuming the Continuum Hypothesis (CH),¹ this result implies that for the aforementioned colouring of \mathbb{R} , every uncountable subset X is such that $\text{FS}_2(X)$ is not monochromatic.

In this paper we shall consider stronger versions of these results, where colourings of uncountable commutative cancellative semigroups G are obtained, with more than two colours, satisfying that for every

¹CH asserts that $|\mathbb{R}| = \omega_1$, that is, that there do not exist any cardinalities strictly between that of \mathbb{N} and that of \mathbb{R} .

uncountable X not only is $\text{FS}(X)$ not monochromatic, but in fact $\text{FS}(X)$ contains occurrences of every possible colour. In order to properly state our results, we will introduce some new notation, which is inspired by the standard notation from Ramsey theory. Following [5, p. 56], for cardinals $\kappa, \lambda, \theta, \mu$, write

$$\kappa \rightarrow [\lambda]_{\theta}^{\mu}$$

to assert that for every colouring of $[\kappa]^{\mu}$ in θ many colours, it is possible to find an $X \subseteq \kappa$ with $|X| = \lambda$ such that $[X]^{\mu}$ omits at least one of the colours.² Note that the negation of the above, denoted

$$\kappa \nrightarrow [\lambda]_{\theta}^{\mu},$$

asserts the existence of a colouring $c : [\kappa]^{\mu} \rightarrow \theta$ such that for every λ -sized subset X of κ , we have $c''[X]^{\mu} = \theta$. So Ramsey's theorem is just the assertion that $\omega \rightarrow [\omega]_2^2$ holds, however, when ω is replaced by larger cardinals, typically one gets negative relations, sometimes quite strong (i.e., involving a large number of colours). Negative square bracket partition relations have been studied extensively. For instance, in the realm of ω_1 , we have a sequence of results starting with Sierpiński's uncountable poset [30] that admits no uncountable chains nor uncountable antichains, thereby, witnessing $\omega_1 \nrightarrow [\omega_1]_2^2$. Later, Blass [1] improved this to $\omega_1 \nrightarrow [\omega_1]_3^2$, and Galvin and Shelah [10] improved further to $\omega_1 \nrightarrow [\omega_1]_4^2$. Then, Todorćević [33] managed to gain control on the maximal number of colours, proving that $\omega_1 \nrightarrow [\omega_1]_{\omega_1}^2$ holds. Recently, even more complicated statements were proven by Moore [20] and Peng and Wu [21].

In analogy with the above, we now define a negative partition relation for commutative semigroups, involving finite sums (FS), bounded finite sums (FS_n), and sumsets (SuS).

Definition. For a commutative semigroup G , cardinals λ, θ , and an integer n :

- (1) $G \nrightarrow [\lambda]_{\theta}^{\text{FS}}$ asserts the existence of a colouring $c : G \rightarrow \theta$ such that for every λ -sized subset X of G , we have $c[\text{FS}(X)] = \theta$;
- (2) $G \nrightarrow [\lambda]_{\theta}^{\text{FS}_n}$ asserts the existence of a colouring $c : G \rightarrow \theta$ such that for every λ -sized subset X of G , we have $c[\text{FS}_n(X)] = \theta$, where $\text{FS}_n(X) := \{x_1 + \dots + x_n \mid x_1, \dots, x_n \in X \text{ are all distinct}\}$;
- (3) $G \nrightarrow [\lambda]_{\theta}^{\text{SuS}}$ asserts the existence of a colouring $c : G \rightarrow \theta$ such that for every integer $m \geq 2$, and every λ -sized subsets X_1, \dots, X_m of G , we have $c[X_1 + \dots + X_m] = \theta$, where $X_1 + \dots + X_m := \{x_1 + \dots + x_m \mid \forall i (x_i \in X_i)\}$.

Note that for all $\lambda \leq \lambda', G \subseteq G', \theta \leq \theta'$, and $\mathbf{x} \in \{\text{FS}_n, \text{FS}, \text{SuS} \mid n < \omega\}$, $G' \nrightarrow [\lambda']_{\theta'}^{\mathbf{x}}$ implies $G \nrightarrow [\lambda]_{\theta}^{\mathbf{x}}$. Also note that for every n , $G \nrightarrow [\lambda]_{\theta}^{\text{FS}_n}$ implies $G \nrightarrow [\lambda]_{\theta}^{\text{FS}}$. Finally, note that for every infinite cardinal λ and every integer $n \geq 2$, $G \nrightarrow [\lambda]_{\theta}^{\text{SuS}}$ implies $G \nrightarrow [\lambda]_{\theta}^{\text{FS}_n}$ simply because any infinite set X may be partitioned into $\biguplus_{i=1}^n X_i$ in such a way that $|X_i| = |X|$ for all i . And indeed, $G \nrightarrow [\lambda]_{\theta}^{\text{SuS}}$ will be the strongest negative partition relation considered in this paper.

Using the above notation, we can now succinctly state the relevant web of results (in chronological order):

- The generalized Hindman theorem (see [14, Corollary 5.9]) asserts that $G \rightarrow [\omega]_2^{\text{FS}}$ holds (that is, $G \nrightarrow [\omega]_2^{\text{FS}}$ fails) for every infinite commutative cancellative semigroup G ;³
- Milliken [19] proved that $G \nrightarrow [\kappa^+]_{\kappa^+}^{\text{FS}_2}$ holds whenever $|G| = \kappa^+ = 2^{\kappa}$ for some infinite cardinal κ ;⁴
- Hindman, Leader and Strauss [13, Theorem 3.2] proved that $\mathbb{R} \nrightarrow [\mathfrak{c}]_2^{\text{FS}_n}$ holds for every integer $n \geq 2$;
- The first author [6] proved that $G \nrightarrow [\omega_1]_2^{\text{FS}}$ holds for every uncountable commutative cancellative semigroup G ;
- Komjáth [18], and independently Soukup and Weiss [31], proved that $\mathbb{R} \nrightarrow [\omega_1]_2^{\text{FS}_n}$ holds for every integer $n \geq 2$. They also pointed out [31, Corollary 2.3] that by a theorem of Shelah [27, Theorem 2.1], it is consistent with ZFC (modulo a large cardinal hypothesis) that $\mathbb{R} \nrightarrow [\omega_1]_3^{\text{FS}_n}$ fails for every $n \geq 2$.

The main results of this paper read as follows:

²Here, $[X]^{\mu}$ stands for the collection of all subsets of X of cardinality μ , where in the case that X is a set of ordinals, we identify these μ -sized subsets with their increasing enumeration. In particular, $[\kappa]^2 = \{\langle \alpha, \beta \rangle \mid \alpha < \beta < \kappa\}$.

³Consequently, $G \rightarrow [\omega]_n^{\text{FS}}$ holds for every $n < \omega$.

⁴However, it is consistent with ZFC that $2^{\kappa} > \kappa^+$ for every infinite cardinal κ [7].

Theorem A. $G \not\rightarrow [\omega_1]_\omega^{\text{FS}}$ holds for every uncountable commutative cancellative semigroup G .

We shall show that the superscript FS in the preceding is optimal, by exhibiting an uncountable abelian group G for which $G \not\rightarrow [\omega_1]_\omega^{\text{FS}_n}$ fails for all n . We shall also address a stronger form of Theorem A, proving that things can go both ways:

Theorem B1. *It is consistent with ZFC that $G \not\rightarrow [\omega_1]_{\omega_1}^{\text{FS}}$ holds for every uncountable commutative cancellative semigroup G .*

Theorem B2. *Modulo a large cardinal hypothesis, it is consistent with ZFC that $\mathbb{R} \not\rightarrow [\omega_1]_{\omega_1}^{\text{FS}}$ fails.*

It turns out that partition relations for FS_n sets can also go both ways. To exemplify on the real line:

Theorem C1. *If \mathfrak{c} is a successor cardinal (e.g., assuming CH), then $\mathbb{R} \not\rightarrow [\mathfrak{c}]_{\omega_1}^{\text{SuS}}$ holds, and hence, so does $\mathbb{R} \not\rightarrow [\mathfrak{c}]_{\omega_1}^{\text{FS}_n}$ for every integer $n \geq 2$.*

Theorem C2. *Modulo a large cardinal hypothesis, it is consistent with ZFC that $\mathbb{R} \not\rightarrow [\omega_1]_{\omega_1}^{\text{FS}_n}$ fails for every integer $n \geq 2$.*

The preceding raises the question of which negative partition relations for \mathbb{R} are consequences of ZFC. For this, we have the following simultaneous generalization of [10, Theorem 1] and [13, Theorem 3.2]:

Theorem C3. $\mathbb{R} \not\rightarrow [\mathfrak{c}]_\omega^{\text{FS}_n}$ holds for every integer $n \geq 2$.

Finally, we establish that the negative partition relation of the strongest form is quite a prevalent phenomena:

Theorem D. *Denote by \otimes_κ the assertion that $G \not\rightarrow [\kappa]_\kappa^{\text{SuS}}$ holds for every commutative cancellative semigroup G of cardinality κ . Then:*

- \otimes_κ holds for $\kappa = \aleph_1, \aleph_2, \dots, \aleph_n, \dots$; In fact, \otimes_κ holds for every κ which is a successor of regular cardinal;
- \otimes_κ holds whenever $\kappa = \lambda^+ = 2^\lambda$ or whenever κ is a regular uncountable cardinal admitting a nonreflecting stationary set. In particular:
- It is consistent with ZFC that \otimes_κ holds for every regular uncountable cardinal κ .

Organization of this paper. Theorems A, B1 and B2 are proved in Section 2. In Section 3, we establish some new results on the partition calculus of uncountable cardinals. In Section 4, the machinery of Section 3 is invoked in proving, among other things, Theorem D. Section 5 focuses on the real line, and Theorems C1, C2, C3 are derived there as corollaries.

2. COLOURINGS FOR FINITE SUMS

We open this section by stating a structural result that will allow us to pass from elements of commutative cancellative semigroups of cardinality κ to finite subsets of κ , so that we are able to apply some machinery from partition relations on cardinals to our semigroups.⁵ For this, we will need to lay down some terminology.

Definition 2.1. Given a sequence of groups $\langle G_\alpha \mid \alpha < \kappa \rangle$, define its *direct sum* to be the group

$$\bigoplus_{\alpha < \kappa} G_\alpha := \left\{ x \in \prod_{\alpha < \kappa} G_\alpha \mid x(\alpha) \text{ equals the identity for all but finitely many } \alpha \right\}.$$

Recall that a *divisible group* is an abelian group G such that for every $x \in G$ and every $n \in \mathbb{N}$, there exist some $z \in G$ such that $nz = x$.

Lemma 2.2. *Suppose that G is an infinite commutative cancellative semigroup. Denote $\kappa := |G|$. Then there exists a sequence of countable divisible groups, $\langle G_\alpha \mid \alpha < \kappa \rangle$, such that G embeds in $\bigoplus_{\alpha < \kappa} G_\alpha$.*

⁵The noncommutative case will be handled in a forthcoming paper.

Proof. It is well-known that every commutative cancellative semigroup G can be embedded in an abelian group G' , which can furthermore be assumed to have the same cardinality as G .⁶ Next, since G' is an abelian group, it can be embedded in a divisible group G'' , by [8, Theorem 24.1]. Finally, by [8, Theorem 23.1], each divisible group is isomorphic to a direct sum of some copies of \mathbb{Q} with some quasicyclic groups $\mathbb{Z}(p^\infty)$.⁷ Thus, we may assume that $G'' = \bigoplus_{\alpha < \lambda} G_\alpha$, where each G_α is equal to either \mathbb{Q} , or $\mathbb{Z}(p^\infty)$. By removing spurious summands (i.e., the $\alpha < \lambda$ such that $x(\alpha) = 0$ for every $x \in G$) we can assume that the number of summands is $|G|$, in other words, that $\lambda = \kappa$. Thus, G embeds into $\bigoplus_{\alpha < \kappa} G_\alpha$, and each G_α (being either \mathbb{Q} or $\mathbb{Z}(p^\infty)$ for some p) is a countable divisible group. \square

In what follows, given an infinite commutative cancellative semigroup G of infinite cardinality κ , we will always implicitly fix an embedding of G into $\bigoplus_{\alpha < \kappa} G_\alpha$, where each G_α is countable, as per Lemma 2.2. This allows us to define the *support* of an element $x \in G$ to be the finite set

$$\text{supp}(x) := \{\alpha < \kappa \mid x(\alpha) \neq 0\}.$$

Definition 2.3. A family of sets \mathcal{X} is said to be a Δ -system with root r if for every two distinct $x, x' \in \mathcal{X}$, we have $x \cap x' = r$.

A Δ -system \mathcal{X} is said to be of the *head-tail-tail* form if:

- $\text{sup}(r) < \min(x \setminus r)$ for all $x \in \mathcal{X}$;
- for any two distinct $x, x' \in \mathcal{X}$, either $\text{sup}(x) < \min(x' \setminus r)$ or $\text{sup}(x') < \min(x \setminus r)$.

A standard fact from Set Theory states that for every regular uncountable cardinal κ and every family \mathcal{X} consisting of κ many finite sets, there exists $\mathcal{X}' \subseteq \mathcal{X}$ with $|\mathcal{X}'| = \kappa$ such that \mathcal{X}' forms a Δ -system. In the special case that $\mathcal{X} \subseteq [\kappa]^{<\omega}$, a Δ -subsystem $\mathcal{X}' \subseteq \mathcal{X}$ may be found which is moreover of the head-tail-tail form.

Proposition 2.4. Suppose that x_1, \dots, x_n are elements of a direct sum $\bigoplus_{\alpha < \kappa} G_\alpha$, and there exist a fixed $r \in [\kappa]^{<\omega}$ and pairwise disjoint $s_1, \dots, s_n \in [\kappa]^{<\omega}$ satisfying $\text{supp}(x_i) = r \uplus s_i$ for all $1 \leq i \leq n$ (that is, the set of corresponding supports forms a Δ -system with root r). Then

$$s_1 \cup \dots \cup s_n \subseteq \text{supp}(x_1 + \dots + x_n) \subseteq r \cup s_1 \cup \dots \cup s_n.$$

Proof. Let $\alpha < \kappa$ be arbitrary. If $\alpha \notin r \cup s_1 \cup \dots \cup s_n$, then $\alpha \notin \text{supp}(x_i)$ for any i , thus

$$(x_1 + \dots + x_n)(\alpha) = x_1(\alpha) + \dots + x_n(\alpha) = 0 + \dots + 0 = 0,$$

therefore $\text{supp}(x_1 + \dots + x_n) \subseteq r \cup s_1 \cup \dots \cup s_n$. Now, if $\alpha \in s_1 \cup \dots \cup s_n$, then there exists a unique $1 \leq i \leq n$ with $\alpha \in s_i$. This means that $\alpha \in \text{supp}(x_i)$ but $\alpha \notin \text{supp}(x_j)$ for $j \neq i$, in other words, $x_i(\alpha) \neq 0$ but $x_j(\alpha) = 0$ for $j \neq i$. Therefore

$$\begin{aligned} (x_1 + \dots + x_n)(\alpha) &= x_1(\alpha) + \dots + x_{i-1}(\alpha) + x_i(\alpha) + x_{i+1}(\alpha) + \dots + x_n(\alpha) \\ &= 0 + \dots + 0 + x_i(\alpha) + 0 + \dots + 0 = x_i(\alpha) \neq 0, \end{aligned}$$

thus $s_1 \cup \dots \cup s_n \subseteq \text{supp}(x_1 + \dots + x_n)$. \square

The main offshot of Proposition 2.4 is that, whenever we want to determine $\text{supp}(x_1 + \dots + x_n)$ for x_1, \dots, x_n satisfying the corresponding hypothesis, the only coordinates α that require careful inspection are the $\alpha \in r$, where one must determine whether $x_1(\alpha) + \dots + x_n(\alpha)$ is equal to 0. In the particular case where $n = 2$, we obtain the fact, which will be useful later, that

$$\text{supp}(x_1) \Delta \text{supp}(x_2) \subseteq \text{supp}(x_1 + x_2) \subseteq \text{supp}(x_1) \cup \text{supp}(x_2).$$

In [6, Theorem 5], it was established that for every uncountable commutative cancellative semigroup G , $G \twoheadrightarrow [\omega_1]_2^{\text{FS}}$. This was done by colouring an element $x \in G$ according to the parity of $|\log_2 |\text{supp}(x)||$.⁸

⁶This is done by means of the same process which embeds the additive group \mathbb{N} into \mathbb{Z} , or the multiplicative group $\mathbb{Z} \setminus \{0\}$ into $\mathbb{Q} \setminus \{0\}$. This process yields G' as a quotient of the semigroup $G \times G$, therefore $|G'| = |G|$.

⁷Recall that for a prime number p , the p -quasicyclic group (also known as the Prüfer p -group) is a countable divisible subgroup of \mathbb{R}/\mathbb{Z} , defined by $\mathbb{Z}(p^\infty) := \left\{ \frac{a}{p^n} + \mathbb{Z} \mid a \in \mathbb{Z} \text{ \& } n < \omega \right\}$.

⁸The idea of colouring a finite set F according to the parity of $|\log_2 |F||$ goes back to [2].

Similarly, for every uncountable commutative cancellative semigroup G and every positive integer m , it is possible to define a colouring $c : G \rightarrow m$ by declaring $c(x)$ to be the class of $\lfloor \log_2 |\text{supp}(x)| \rfloor$ modulo m . Arguing in the same way as in the proof of [6, Theorem 5], one can show that every uncountable $X \subseteq G$ satisfies $c[\text{FS}(X)] = m$; so that every uncountable commutative cancellative semigroup G satisfies $G \nrightarrow [\omega_1]_m^{\text{FS}}$ for every $m < \omega$. In this section, among other things, we will show that every uncountable commutative cancellative semigroup G moreover satisfies $G \nrightarrow [\omega_1]_\omega^{\text{FS}}$.

In order to simplify certain steps of the proof of the main theorem, let us introduce the following notion.

Definition 2.5. Let G be a commutative semigroup, and $X \subseteq G$.

We say that Y is a *condensation* of X if there exists a family $\mathcal{A} \subseteq [X]^{<\omega}$ consisting of pairwise disjoint sets, such that

$$Y = \left\{ \sum_{x \in a} x \mid a \in \mathcal{A} \right\}.$$

The importance of this notion stems from the evident fact that if Y is a condensation of X , then $\text{FS}(Y) \subseteq \text{FS}(X)$. Thus the notion of “passing to a condensation” constitutes another, purely algebraic, form of thinning-out a family of elements of G which can be useful if we are dealing with finite sums without restrictions on the number of summands.

The following argument was first used in [6] (in the proof of the Claim within the proof of Theorem 5 therein), and is encapsulated here as a lemma both for the convenience of the reader, and for future reference.

Lemma 2.6. *Suppose that G is a commutative cancellative semigroup, and $X \subseteq G$ is a subset of regular uncountable cardinality. Fix an embedding of G into a direct sum $\bigoplus_{\alpha < \kappa} G_\alpha$, as per Lemma 2.2.*

Then there exists a condensation Y of X such that:

- $\text{supp}[Y] := \{\text{supp}(y) \mid y \in Y\}$ forms a Δ -system of cardinality $|X|$;
- for all $y \in Y$ and all α in the root of $\text{supp}[Y]$, $y(\alpha)$ has an infinite order in G_α ;
- for every positive integer n and every $y_1, \dots, y_n \in Y$,

$$\text{supp}(y_1 + \dots + y_n) = \text{supp}(y_1) \cup \dots \cup \text{supp}(y_n).$$

Proof. Note that as $x \mapsto \{\langle \alpha, x(\alpha) \rangle \mid \alpha \in \text{supp}(x)\}$ is an injection, and each G_α is countable, we have $|\text{supp}[Y]| = |Y|$ for every uncountable $Y \subseteq X$. In particular, $|\text{supp}[X]|$ is regular and uncountable, and by passing to an equipotent subset of X , we may assume that $\text{supp}[X]$ forms a Δ -system.

Let r denote the root of this system. If r is empty, then we are done, as a consequence of Proposition 2.4. Thus, suppose that r is nonempty. Now, a finite number of applications of the pigeonhole principle allows us to thin out X , without changing its cardinality, in such a way that for every $\alpha \in r$, there exists a fixed $g_\alpha \in G_\alpha$ such that $x(\alpha) = g_\alpha$ for all $x \in X$. Let $r_\infty := \{\alpha \in r \mid g_\alpha \text{ is of infinite order}\}$, and $M := \{\text{ord}(g_\alpha) \mid \alpha \in r \setminus r_\infty\}$. Since r is finite, so is M , thus we can take $m := \prod_{n \in M} n$ (in the understanding that the empty product equals 1), thereby ensuring that $mg_\alpha = 0$ for all $\alpha \in r \setminus r_\infty$. Now we obtain a condensation Y of X , by fixing some family $\mathcal{A} \subseteq [X]^m$ consisting of exactly $|X|$ many pairwise disjoint m -sized sets, and then letting

$$Y := \left\{ \sum_{x \in a} x \mid a \in \mathcal{A} \right\}.$$

Claim 2.6.1. $\text{supp}[Y]$ forms a Δ -system of cardinality $|X|$ with root r_∞ .

Proof. For each $x \in X$, denote $s_x := \text{supp}(x) \setminus r$, so that $\{s_x \mid x \in X\}$ is a family of pairwise disjoint sets. Now, for any $y \in Y$, there is an $a \in \mathcal{A}$ (with $|a| = m$) such that $y = \sum_{x \in a} x$, and we claim that

$$\text{supp}(y) = r_\infty \uplus \left(\bigcup_{x \in a} s_x \right).$$

This will show that $\text{supp}[Y]$ forms a Δ -system with root r_∞ . This will also show that the map $a \mapsto \text{supp}(\sum_{x \in a} x)$ is an injection from \mathcal{A} to $\text{supp}[Y]$, so that $|\text{supp}[Y]| = |\mathcal{A}| = |X|$.

Here goes. By Proposition 2.4, we know that $\bigcup_{x \in a} s_x \subseteq \text{supp}(y) \subseteq r \cup (\bigcup_{x \in a} s_x)$, thus it suffices to prove that for every $\alpha \in r$: $\alpha \in \text{supp}(y) \iff \alpha \in r_\infty$.

► For each $\alpha \in r_\infty$ and $x \in a$, we have $x(\alpha) = g_\alpha$ which is an element of infinite order. Hence

$$y(\alpha) = \sum_{x \in a} x(\alpha) = mg_\alpha \neq 0.$$

► For each $\alpha \in r \setminus r_\infty$ and $x \in a$, we have $x(\alpha) = g_\alpha$ which is an element whose order is a divisor of m . Hence

$$y(\alpha) = \sum_{x \in a} x(\alpha) = mg_\alpha = 0.$$

Altogether, we have $\text{supp}(y) = r_\infty \uplus (\bigcup_{x \in a} s_x)$.

Finally, given any two distinct $y, y' \in Y$, pick $a, a' \in \mathcal{A}$ such that $y = \sum_{x \in a} x$ and $y' = \sum_{x \in a'} x$. Then by $a \cap a' = \emptyset$ and since the s_x are pairwise disjoint, we have that

$$\text{supp}(y) \cap \text{supp}(y') = \left(r_\infty \cup \bigcup_{x \in a} s_x \right) \cap \left(r_\infty \cup \bigcup_{x \in a'} s_x \right) = r_\infty,$$

which shows that $\text{supp}[Y]$ forms a Δ -system, with root r_∞ . \square

Now let $n \in \mathbb{N}$, and let $y_1, \dots, y_n \in Y$ be n many distinct elements. It remains to prove that $\text{supp}(y_1 + \dots + y_n) = \text{supp}(y_1) \cup \dots \cup \text{supp}(y_n)$. Denote $s_i := \text{supp}(y_i) \setminus r_\infty$. By Proposition 2.4,

$$s_1 \cup \dots \cup s_n \subseteq \text{supp}(y_1 + \dots + y_n) \subseteq r_\infty \cup s_1 \cup \dots \cup s_n = \text{supp}(y_1) \cup \dots \cup \text{supp}(y_n),$$

and therefore it suffices to prove that $r_\infty \subseteq \text{supp}(y_1 + \dots + y_n)$. So let $\alpha \in r_\infty$ be arbitrary. We have already noticed that $y_i(\alpha) = mg_\alpha$ for each $1 \leq i \leq n$, where g_α is an element of infinite order. Consequently

$$(y_1 + \dots + y_n)(\alpha) = y_1(\alpha) + \dots + y_n(\alpha) = mg_\alpha + \dots + mg_\alpha = (nm)g_\alpha \neq 0,$$

which shows that $\alpha \in \text{supp}(y_1 + \dots + y_n)$, and we are done. \square

We now arrive at the main technical result of this section.

Theorem 2.7. *Suppose that G is a commutative cancellative semigroup of uncountable cardinality κ .*

Then there exists a transformation $d : G \rightarrow [\kappa]^{<\omega}$ with the property that for every uncountable $X \subseteq G$, there exists $A \subseteq \kappa$ such that $|A| = |X|$ and $d^{\text{FS}}(X) \supseteq [A]^{<\omega}$.

Proof. We commence with an easy observation.

Claim 2.7.1. *There exists a surjection $f : \omega \rightarrow [\omega]^{<\omega}$ satisfying the two:*

- for all $k < \omega$, $f(k) \subseteq k$;
- for all $m, n < \omega$ and $\Omega \in [\omega]^{<\omega}$, there are infinitely many $k < \omega$ such that $f(m + nk) = \Omega$.

Proof. For all $m, n, a, b < \omega$, the set

$$D(m, n, a, b) := \{\varphi \in {}^\omega \omega \mid \exists k < \omega [k \geq a \ \& \ \varphi(m + nk) = b]\}$$

is dense open in the Baire space ${}^\omega \omega$. So, by the Baire category theorem, $\bigcap \{D(m, n, a, b) \mid m, n, a, b < \omega\} \neq \emptyset$. Pick φ from that intersection, along with an arbitrary surjection $\psi : \omega \rightarrow [\omega]^{<\omega}$. Then, define $f : \omega \rightarrow [\omega]^{<\omega}$, by stipulating

$$f(k) := \begin{cases} (\psi \circ \varphi)(k), & \text{if } (\psi \circ \varphi)(k) \subseteq k, \\ 0, & \text{otherwise.} \end{cases}$$

Clearly, f is as sought. \square

Fix f as in the preceding. For every finite set of ordinals z , let us denote by $\sigma_z : |z| \leftrightarrow z$ the order-preserving bijection, so that $\sigma_z(i)$ stands for the i^{th} -element of z .

Next, embed G into $\bigoplus_{\alpha < \kappa} G_\alpha$, with each G_α a countable abelian group, as per Lemma 2.2. Then, define a colouring $d : G \rightarrow [\kappa]^{<\omega}$ by stipulating:

$$d(x) := \sigma_{\text{supp}(x)} "f(|\text{supp}(x)|).$$

To see that d works, let X be some uncountable subset of G . The proof now splits into two cases, depending on $\lambda := |X|$.

Case 1. Suppose that λ is regular.

Let Y be given by Lemma 2.6 with respect to X . In particular, $\text{supp}[Y]$ forms a Δ -system of cardinality λ , with root, say, r . Denote $m := |r|$. Clearly, by passing to an equipotent subset of Y , we may assume the existence of some positive integer n and a strictly increasing function $h : m \rightarrow m + n$ such that for every $y \in Y$:

- $|\text{supp}(y)| = m + n$, and
- $\sigma_r = \sigma_{\text{supp}(y)} \circ h$.

Let a be the maximal integer $\leq m$ for which $h \upharpoonright a$ is the identity function. In particular, $\sigma_{\text{supp}(y)}[a] = \sigma_r[a]$ for all $y \in Y$.

Claim 2.7.2. *There exist $b < \omega$, $\delta \leq \kappa$, and a sequence $\langle y_i \mid i < \lambda \rangle$ of elements of Y such that:*

- $\{\sigma_{\text{supp}(y_i)}[a + b] \mid i < \lambda\}$ forms a head-tail-tail Δ -system with root $\sigma_r[a]$;
- $i \mapsto \sigma_{\text{supp}(y_i)}(a)$ is strictly-increasing over λ ;
- $\sigma_{\text{supp}(y_i)}[a + b] = \text{supp}(y_i) \cap \delta$ for all $i < \lambda$.

Proof. By the choice of a , for all $y \in Y$, we have $\min(\text{supp}(y) \setminus r) = \sigma_{\text{supp}(y)}(a)$. In particular, $y \mapsto \sigma_{\text{supp}(y)}(a)$ is injective over Y . So, by the Dushnik-Miller theorem, we may pick a sequence $\langle y_i \mid i < \lambda \rangle$ of elements of Y such that $i \mapsto \sigma_{\text{supp}(y_i)}(a)$ is strictly increasing over λ . Put $\delta := \sup\{\sigma_{\text{supp}(y_i)}(a) \mid i < \lambda\}$. Clearly, $\text{cf}(\delta) = \lambda$.

Next, for all $j \leq m + n$, let $\Lambda_j := \{i < \lambda \mid \text{supp}(y_i) \cap \delta = \sigma_{\text{supp}(y_i)}[j]\}$. This defines a partition of λ into finitely many sets, and we may pick some positive integer b such that $|\Lambda_{a+b}| = \lambda$.

Finally, recursively construct a (strictly-increasing) function $g : \lambda \rightarrow \Lambda_{a+b}$ as follows:

- Let $g(0) := \min(\Lambda_{a+b})$;
- If $i < \lambda$ is nonzero and $g \upharpoonright i$ has already been defined, let $\beta := \sup_{j < i} (\text{supp}(y_{g(j)}) \cap \delta)$. By $i < \lambda = \text{cf}(\delta)$, we have $\beta < \delta$, so we may let $g(i) := \min\{j \in \Lambda_{a+b} \mid \sigma_{\text{supp}(y_j)}(a) > \beta\}$.

Clearly, b, δ and the sequence $\langle y_{g(i)} \mid i < \lambda \rangle$ are as sought. \square

Let b, δ and $\langle y_i \mid i < \lambda \rangle$ be as in the statement of the preceding claim. Denote $z_i := \text{supp}(y_i) \setminus (r \cap \delta)$. Notice that $\min(z_i) = \min(\text{supp}(y_i) \setminus r) = \sigma_{\text{supp}(y_i)}(a)$.

Figure 1: Illustration of the system produced by Claim 2.7.2.

We claim that $d^{\text{FS}}(X) \supseteq [A]^{<\omega}$ for the λ -sized set $A := \{\min(z_i) \mid i < \lambda\}$.

To see this, fix an arbitrary $p \in [A]^{<\omega}$. Let $\{\alpha_j \mid j < c\}$ be the increasing enumeration of p , so that $c = |p|$. Set $\Omega := \{a + bj \mid j < c\}$. By the choice of the function f , let us fix some integer $k > c$ such that $f(m + nk) = \Omega$.

Let $\langle i_j \mid j < k \rangle$ be a strictly increasing sequence of ordinals in λ such that for all $j < c$, i_j is the unique ordinal to satisfy $\alpha_j = \min(z_{i_j})$. Put $x := \sum_{j < k} x_j$, where $x_j := y_{i_j}$. By $\{y_{i_j} \mid j < k\} \subseteq Y$, we have:

- $x \in \text{FS}(X)$;
- $\text{supp}(x) = \bigcup_{j < k} \text{supp}(x_j) = r \uplus (\text{supp}(x_0) \setminus r) \uplus \cdots \uplus (\text{supp}(x_{k-1}) \setminus r)$;
- $\text{supp}(x) \cap \delta = \sigma_r[a] \sqcup \sigma_{\text{supp}(x_0)}[a, a + b] \sqcup \cdots \sqcup \sigma_{\text{supp}(x_{k-1})}[a, a + b]$.⁹

⁹Here, $w = z \sqcup z'$ asserts that $w = z \cup z'$ and $\sup(z) < \min(z')$.

In particular, $|\text{supp}(x)| = m + nk > a + bc$, and

$$\begin{aligned} d(x) &= \sigma_{\text{supp}(x)} "f(m + nk) = \sigma_{\text{supp}(x)} " \Omega \\ &= \{\sigma_{\text{supp}(x)}(a + bj) \mid j < c\} \\ &= \{\sigma_{\text{supp}(x_j)}(a) \mid j < c\} = \{\sigma_{\text{supp}(y_{i_j})}(a) \mid j < c\} \\ &= \{\min(z_{i_j}) \mid j < c\} = \{\alpha_j \mid j < c\} = p, \end{aligned}$$

as sought.

Case 2. Suppose that λ is singular.

Let $\langle \lambda_\gamma \mid \gamma < \text{cf}(\lambda) \rangle$ be a strictly increasing sequence of regular cardinals converging to λ , with $\lambda_0 > \text{cf}(\lambda)$. Let $\langle X_\gamma \mid \gamma < \text{cf}(\lambda) \rangle$ be a partition of X with $|X_\gamma| = \lambda_\gamma$ for all $\gamma < \text{cf}(\lambda)$.

For each $\gamma < \text{cf}(\lambda)$, appeal to Lemma 2.6 with X_γ , to obtain a set Y_γ . In particular, $\text{supp}[Y_\gamma]$ forms a Δ -system of cardinality λ_γ , with root, say, r_γ . Let

$$\delta_\gamma := \min\{\delta \leq \kappa \mid |\{\min(\text{supp}(y) \cap (\delta \setminus r_\gamma)) \mid y \in Y_\gamma\}| = \lambda_\gamma\}.$$

Clearly, $\text{cf}(\delta_\gamma) = \lambda_\gamma$. In particular, $\gamma \mapsto \delta_\gamma$ is injective over $\text{cf}(\lambda)$, and we may find some cofinal subset $\Gamma \subseteq \text{cf}(\lambda)$ over which $\gamma \mapsto \delta_\gamma$ is strictly increasing. Put $\delta := \sup_{\gamma \in \Gamma} \delta_\gamma$, and $r := \bigcup_{\gamma \in \Gamma} r_\gamma$.

For all $\gamma \in \Gamma$, by $\lambda_\gamma > \text{cf}(\lambda) = \text{cf}(\delta)$, let us fix a large enough $\beta_\gamma < \delta$ for which

$$Y_\gamma^0 := \{y \in Y_\gamma \mid \min(\text{supp}(y) \setminus r_\gamma) < \delta_\gamma \ \& \ \text{supp}(y) \cap \delta \subseteq \beta_\gamma\}$$

has cardinality λ_γ . Let $\bar{\Gamma}$ be some sparse enough cofinal subset of Γ such that

$$\sup\{\beta_{\gamma'} \mid \gamma' \in \bar{\Gamma} \cap \gamma\} < \delta_\gamma$$

for all $\gamma' < \gamma$ both from $\bar{\Gamma}$.

For all $\gamma \in \Gamma$, by minimality of δ_γ and by $\lambda_\gamma > |[r]^{<\omega}|$, we infer that the following set has size λ_γ :

$$Y_\gamma^1 := \{y \in Y_\gamma^0 \mid (\sup\{\beta_{\gamma'} \mid \gamma' \in \bar{\Gamma} \cap \gamma\} < \min(\text{supp}(y) \setminus r_\gamma)) \ \& \ (y \cap r = r_\gamma)\}.$$

Put $Y := \biguplus_{\gamma \in \bar{\Gamma}} Y_\gamma^1$. For all $y \in Y$, let $\gamma(y)$ denote the unique ordinal $\gamma \in \bar{\Gamma}$ such that $y \in Y_\gamma^1$.

Consider the following subset of δ :

$$A := \{\min(\text{supp}(y) \setminus r_{\gamma(y)}) \mid y \in Y\} \setminus r.$$

Claim 2.7.3. *For each $\alpha \in A$, there exists a unique $y \in Y$ such that $\alpha \in \text{supp}(y)$.*

In particular, $|A| = \lambda$.

Proof. Let $\alpha \in A$ be arbitrary. Fix some $y_\alpha \in Y$ such that $\alpha = \min(\text{supp}(y_\alpha) \setminus r_{\gamma(y_\alpha)})$. Towards a contradiction, suppose that there exists $y \in Y \setminus \{y_\alpha\}$ with $\alpha \in \text{supp}(y)$. There are three cases to consider, each of which leads to a contradiction:

- Suppose that $\gamma(y_\alpha) = \gamma(y)$.

Then $\alpha \in \text{supp}(y_\alpha) \cap \text{supp}(y) \subseteq r_{\gamma(y)} \subseteq r$, contradicting the fact that $A \cap r = \emptyset$.

- Suppose that $\gamma(y_\alpha) \in \bar{\Gamma} \cap \gamma(y)$.

Then $\alpha \in \text{supp}(y_\alpha) \cap \delta \subseteq \beta_{\gamma(y_\alpha)} < \min(\text{supp}(y) \setminus r_{\gamma(y)})$.

So, by $\alpha \in \text{supp}(y)$, it must be the case that $\alpha \in r_{\gamma(y)} \subseteq r$, contradicting the fact that $A \cap r = \emptyset$.

- Suppose that $\gamma(y) \in \bar{\Gamma} \cap \gamma(y_\alpha)$.

Then $\alpha \in \text{supp}(y) \cap \delta \subseteq \beta_{\gamma(y)} < \min(\text{supp}(y_\alpha) \setminus r_{\gamma(y_\alpha)}) = \alpha$. This is a contradiction. \square

To see that $d^{\text{FS}}(X) \geq [A]^{<\omega}$, let p be an arbitrary element of $[A]^{<\omega}$. For each $\alpha \in p$, pick $y_\alpha \in Y$ such that $\min(\text{supp}(y_\alpha) \setminus r_{\gamma(y_\alpha)}) = \alpha$. Write $z := \sum_{\alpha \in p} y_\alpha$.¹⁰ By Claim 2.7.3, we have $p \subseteq \text{supp}(z)$.

Fix a large enough $\gamma \in \bar{\Gamma}$ such that $\gamma > \gamma(y_\alpha)$ for all $\alpha \in p$. Put $\epsilon := \min(\bigcup\{\text{supp}(y) \setminus r_\gamma \mid y \in Y_\gamma^1\})$. By the choice of γ and the definition of Y_γ^1 , we have $p \subseteq \epsilon$.

Next, by $|\prod_{\beta \in r_\gamma} G_\beta| \leq \omega$ and the pigeonhole principle, let us fix an uncountable $Y_\gamma^2 \subseteq Y_\gamma^1$, a sequence $\langle g_\beta \mid \beta \in r_\gamma \rangle$, and a positive integer n , such that for all $y \in Y_\gamma^2$:

¹⁰If $p = \emptyset$, then z stands for 0_G (the identity element of G).

- $y(\beta) = g_\beta$ for all $\beta \in r_\gamma$;
- $|\text{supp}(y) \setminus r_\gamma| = n$.

Let $\beta \in r_\gamma$ be arbitrary. As Y_γ was provided by Lemma 2.6 and β belongs to the root of $\text{supp}[Y_\gamma]$, we get that for all $y \in Y_\gamma^2$, $g_\beta = y(\beta)$ has an infinite order. In particular, $|\{k < \omega \mid z(\beta) + kg_\beta = 0_{G_\beta}\}| \leq 1$.

As r_γ is finite, let us pick a large enough $K < \omega$ such that $\{k < \omega \mid \exists \beta \in r_\gamma [z(\beta) + kg_\beta = 0_{G_\beta}]\} \subseteq K$, so that $z(\beta) + kg_\beta \neq 0_{G_\beta}$ for all $\beta \in r_\gamma$ and $k \geq K$.

Pick an injective sequence $\langle y^i \mid i < K \rangle$ of elements of Y_γ^1 . Write $z' := z + \sum_{i < K} y^i$, and $m := |\text{supp}(z')|$. Put $Y_\gamma^2 := Y_\gamma^1 \setminus \{y^i \mid i < K\}$. Recalling Claim 2.7.3, we infer that for every finite $\mathcal{Y} \subseteq Y_\gamma^2$:

- $p \uplus r_\gamma \subseteq \text{supp}(z' + \sum_{y \in \mathcal{Y}} y)$;
- $|\text{supp}(z' + \sum_{y \in \mathcal{Y}} y)| = m + n|\mathcal{Y}|$;
- $\text{supp}(z') \cap \epsilon$ is an initial segment of $\text{supp}(z' + \sum_{y \in \mathcal{Y}} y)$.

By $p \subseteq \text{supp}(z') \cap \epsilon$, let us fix $\Omega \in [\text{supp}(z') \cap \epsilon]^{<\omega}$ such that $\sigma_{\text{supp}(z') \cap \epsilon} \Omega = p$. By the choice of the function f , let us fix some $k < \omega$ such that $f(m + nk) = \Omega$. Pick $\mathcal{Y} \in [Y_\gamma^2]^k$, and set $x := z' + \sum_{y \in \mathcal{Y}} y$.

Then $x \in \text{FS}(X)$, $|\text{supp}(x)| = m + nk$, and

$$\begin{aligned} d(x) &= \sigma_{\text{supp}(x)} f(m + nk) = \sigma_{\text{supp}(x)} \Omega \\ &= (\sigma_{\text{supp}(x)} \upharpoonright |\text{supp}(z') \cap \epsilon|) \Omega \\ &= \sigma_{\text{supp}(z') \cap \epsilon} \Omega = p, \end{aligned}$$

as sought. \square

Corollary 2.8. *For every uncountable cardinals $\lambda \leq \kappa$ and a cardinal θ , the following are equivalent:*

- (1) $\kappa \nrightarrow [\lambda]_\theta^{<\omega}$ holds;
- (2) $G \nrightarrow [\lambda]_\theta^{\text{FS}}$ holds for every commutative cancellative semigroup G of cardinality κ ;
- (3) $G \nrightarrow [\lambda]_\theta^{\text{FS}}$ holds for some commutative cancellative semigroup G of cardinality κ .

Proof. (1) \implies (2) Suppose that λ, κ, θ are as above, and that $c : [\kappa]^{<\omega} \rightarrow \theta$ witnesses $\kappa \nrightarrow [\lambda]_\theta^{<\omega}$. That is, for every $A \in [\kappa]^\lambda$, we have $c[A]^{<\omega} = \theta$. Now, given a commutative cancellative semigroup G of cardinality κ , let $d : G \rightarrow [\kappa]^{<\omega}$ be given by Theorem 2.7. Clearly, $c \circ d$ witnesses $G \nrightarrow [\lambda]_\theta^{\text{FS}}$.

(2) \implies (3) This is trivial.

(3) \implies (1) Suppose that G is a commutative cancellative semigroup of cardinality κ , and that $d : G \rightarrow \theta$ is a colouring witnessing $G \nrightarrow [\lambda]_\theta^{\text{FS}}$. Fix an injective enumeration $\{x_\alpha \mid \alpha < \kappa\}$ of the elements of G , and define $c : [\kappa]^{<\omega} \rightarrow \theta$ by stipulating $c(\{\alpha_0, \dots, \alpha_n\}) := d(x_{\alpha_0} + \dots + x_{\alpha_n})$. Clearly, c witnesses $\kappa \nrightarrow [\lambda]_\theta^{<\omega}$. \square

Recall that $(\kappa, \mu) \rightarrow (\lambda, \theta)$ asserts that for every structure (A, R, \dots) for a countable first-order language with a distinguished unary predicate, if $(|A|, |R|) = (\kappa, \mu)$, then there exists an elementary substructure $(B, S, \dots) \prec (A, R, \dots)$ with $(|B|, |S|) = (\lambda, \theta)$.

To exemplify, let us point out that if θ is an infinite cardinal and there exists a θ^+ -Kurepa tree, then $(\theta^{++}, \theta^+) \nrightarrow (\theta^+, \theta)$ fails. Also note that the instance $(\omega_2, \omega_1) \rightarrow (\omega_1, \omega)$ is known as *Chang's conjecture*.

Corollary 2.9. *For every infinite regular cardinal θ and every cardinal $\kappa > \theta$, the following are equivalent:*

- $(\kappa, \theta^+) \rightarrow (\theta^+, \theta)$ fails;
- $G \nrightarrow [\theta^+]_{\theta^+}^{\text{FS}}$ holds for every commutative cancellative semigroup G of cardinality κ .

Proof. By a standard coding argument (using Skolem functions), the failure of $(\kappa, \theta^+) \rightarrow (\theta^+, \theta)$ is equivalent to $\kappa \nrightarrow [\theta^+]_{\theta^+}^{<\omega}$.¹¹ Thus, recalling Corollary 2.8, it suffices to prove that $\kappa \nrightarrow [\theta^+]_{\theta^+}^{<\omega}$ is equivalent to $\kappa \nrightarrow [\theta^+]_{\theta^+}^{\text{FS}}$. Of course, only the forward implication requires an argument. Now, as θ is regular, we get from [33] that $\theta^+ \nrightarrow [\theta^+]_{\theta^+}^2$ holds. Then, as shown in [29], the conjunction of $\kappa \nrightarrow [\theta^+]_{\theta^+}^{<\omega}$ with $\theta^+ \nrightarrow [\theta^+]_{\theta^+}^2$ entails $\kappa \nrightarrow [\theta^+]_{\theta^+}^{<\omega}$. \square

Corollary 2.10. *For every uncountable commutative cancellative semigroup G , $G \nrightarrow [\omega_1]_\omega^{\text{FS}}$ holds.*

¹¹For a proof, see Theorem 8.1 of [17].

Proof. The map $z \mapsto |z|$ witnesses that $\kappa \nrightarrow [\omega]_\omega^{<\omega}$ holds for every infinite cardinal κ . In particular, $\kappa \nrightarrow [\omega_1]_\omega^{<\omega}$ holds for every uncountable cardinal κ . Now, appeal to Corollary 2.8 with $\lambda = \omega_1$ and $\theta = \omega$. \square

Modulo a large cardinal hypothesis, the preceding is optimal:

Proposition 2.11. *If there exists an ω_1 -Erdős cardinal, then in some forcing extension, $\mathbb{R} \nrightarrow [\omega_1]_{\omega_1}^{\text{FS}}$ fails. Furthermore, in this forcing extension, for every semigroup $(G, *)$ of size continuum and every colouring $c : G \rightarrow \omega_1$, there exists an uncountable subset $X \subseteq G$ for which $\{c(x_0 * \dots * x_n) \mid n < \omega, x_0, \dots, x_n \in X\}$ is countable.*

Proof. Let κ denote the ω_1 -Erdős cardinal. So κ is strongly inaccessible and satisfies that for every $\theta < \kappa$ and every colouring $d : [\kappa]^{<\omega} \rightarrow \theta$, there exists some $H \in [\kappa]^{\omega_1}$ such that $d \restriction [H]^n$ is constant for all $n < \omega$.

Let \mathbb{P} denote the notion of forcing for adding κ many Cohen reals. We claim that the forcing extension V is as sought.

Suppose that \dot{c} is a \mathbb{P} -name for a colouring $c : G \rightarrow \omega_1$ of a given semigroup $(G, *)$ of size continuum. As $V \models \mathfrak{c} = \kappa$, let us simplify the matter and just assume that the underlying set G is in fact κ .

Working in V , define a colouring $d : [\kappa]^{<\omega} \rightarrow [\omega_1]^{<\omega}$ by letting for all $n < \omega$ and all $\alpha_0 < \dots < \alpha_n < \kappa$:

$$d(\alpha_0, \dots, \alpha_n) := \{\delta < \omega_1 \mid \exists \sigma : \{0, \dots, n\} \rightarrow \{0, \dots, n\} \exists p \in \mathbb{P}[p \Vdash \text{"}\dot{c}(\check{\alpha}_{\sigma(0)} * \dots * \check{\alpha}_{\sigma(n)}) = \check{\delta}\text{"}]\}.$$

As \mathbb{P} is *ccc*, the range of d indeed consists of *countable* subsets of ω_1 . As κ is an ω_1 -Erdős cardinal, $|[\omega_1]^{<\omega}| < \kappa$ and we may pick some $H \in [\kappa]^{\omega_1}$ such that $d \restriction [H]^n$ is a singleton, say $\{A_n\}$, for every positive integer n . Then H is an uncountable subset of G , $A := \bigcup_{n=1}^{\infty} A_n$ is a countable subset of ω_1 , and

$$\Vdash \text{"}\forall n \in \check{\omega} \forall x_0, \dots, x_n \in \check{H} [\dot{c}(\check{x}_0 * \dots * \check{x}_n) \in \check{A}]\text{"}. \quad \square$$

It is also consistent that the number of colours in Corollary 2.10 *may* be increased to the maximal possible value. To see this, simply take θ to be ω_1 in the next statement:

Corollary 2.12. *It is consistent with ZFC + GCH that for every commutative cancellative semigroup G , $G \nrightarrow [\theta]_\theta^{\text{FS}}$ holds for every uncountable cardinal θ .*

Proof. If there exists an inaccessible cardinal in Gödel's constructible universe L , then let μ denote the least such one and work in L_μ . Otherwise, work in L .

In both cases, we end up with a model of ZFC + GCH [11], satisfying $\kappa \nrightarrow [\theta]_\theta^{<\omega}$ for every uncountable cardinals $\theta \leq \kappa$ [29]. Now, appeal to Corollary 2.8. \square

The preceding is quite surprising (think of the instance $|G| = \beth_{\theta+\omega}$), but of course we are standing on the shoulders of Rowbottom [26].

3. A SET-THEORETIC INTERLUDE

This section is dedicated to study of the following new set-theoretic principles:

Definition 3.1. For infinite cardinals $\chi \leq \kappa$, and an arbitrary cardinal $\theta \leq \kappa$:

- $S(\kappa, \theta)$ asserts the existence of a colouring $d : [\kappa]^{<\omega} \rightarrow \theta$ satisfying the following. For every κ -sized family $\mathcal{X} \subseteq [\kappa]^{<\omega}$ and every $\delta < \theta$, there exist two distinct $x, y \in \mathcal{X}$ such that $d(z) = \delta$ whenever $(x \triangle y) \subseteq z \subseteq (x \cup y)$;
- $S^*(\kappa, \theta, \chi)$ asserts the existence of a colouring $d : [\kappa]^{<\chi} \rightarrow \theta$ satisfying the following. For every integer $n \geq 2$, every sequence $\langle \mathcal{X}_i \mid i < n \rangle \in \prod_{i < n} [[\kappa]^{<\chi}]^\kappa$, and every $\delta < \theta$, there exists $\langle x_i \mid i < n \rangle \in \prod_{i < n} \mathcal{X}_i$ such that $\langle \sup(x_i) \mid i < n \rangle$ is strictly increasing, and such that $d(z) = \delta$ whenever

$$\bigcup_{i < n} \left(x_i \setminus \bigcup_{j \in n \setminus \{i\}} x_j \right) \subseteq z \subseteq \bigcup_{i < n} x_i.$$

Hindman's theorem is well-known to be equivalent to a Ramsey-theoretic statement concerning block sequences. Thus, the reader may want to observe that whenever $d : [\kappa]^{<\omega} \rightarrow \theta$ witnesses $S(\kappa, \theta)$, then for every block sequence $\vec{x} = \langle x_\alpha \mid \alpha < \kappa \rangle$ of finite subsets of κ (i.e., satisfying $\max(x_\alpha) < \min(x_\beta)$ for all $\alpha < \beta < \kappa$), we have $d \text{ "FU"}(\vec{x}) = \theta$ (indeed, for every $\delta < \theta$, there exist $\alpha < \beta < \kappa$ such that $d(x_\alpha \cup x_\beta) = \delta$). Observe that if d furthermore witnesses $S^*(\kappa, \theta, \omega)$, then for every positive $n < \omega$ and every $\delta < \theta$, there exist $\alpha_0 < \dots < \alpha_n < \kappa$ such that $d(x_{\alpha_0} \cup \dots \cup x_{\alpha_n}) = \delta$.

Proposition 3.2. *For all infinite $\chi \leq \chi' \leq \kappa$, and all $\theta \leq \theta' \leq \kappa$:*

- (1) $S^*(\kappa, \theta', \chi')$ entails $S^*(\kappa, \theta, \chi)$;
- (2) $S^*(\kappa, \theta, \chi)$ entails $\kappa \nrightarrow [\kappa; \kappa]_\theta^2$;
- (3) $S^*(\kappa, \theta, \chi)$ entails $S(\kappa, \theta)$;
- (4) $S(\kappa, \theta)$ entails $\kappa \nrightarrow [\kappa]_\theta^2$.

Proof. (1) This is obvious.

(2) Let $d : [\kappa]^{<\chi} \rightarrow \theta$ be a witness to $S^*(\kappa, \theta, \chi)$. Define $c : [\kappa]^2 \rightarrow \theta$ by letting $c(\alpha, \beta) := d(\{\alpha, \beta\})$. Now, suppose that we are given $X, Y \in [\kappa]^\kappa$. We need to verify that for all $\delta < \theta$, there exist $\alpha \in X$ and $\beta \in Y$ such that $\alpha < \beta$ and $c(\alpha, \beta) = \delta$. Put $\mathcal{X} := \{\{\alpha\} \mid \alpha \in X\}$ and $\mathcal{Y} := \{\{\beta\} \mid \beta \in Y\}$. Fix $x \in \mathcal{X}$ and $y \in \mathcal{Y}$ such that $\sup(x) < \sup(y)$ and $d(z) = \delta$ whenever $(x \triangle y) \subseteq z \subseteq (x \cup y)$. Let $\alpha := \sup(x)$ and $\beta := \sup(y)$. Then $\alpha \in X$, $\beta \in Y$, $\alpha < \beta$ and $c(\alpha, \beta) = \delta$, as sought.

(3) Let $d : [\kappa]^{<\chi} \rightarrow \theta$ be a witness to $S^*(\kappa, \theta, \chi)$. We claim that $d \upharpoonright [\kappa]^{<\omega}$ witnesses $S(\kappa, \theta)$. To avoid trivialities, suppose that $\theta > 1$. In particular, by Clause (2) and Ramsey's theorem, κ is uncountable.

Given a κ -sized family $\mathcal{X} \subseteq [\kappa]^{<\omega}$, pick a partition $\mathcal{X} = \mathcal{X}_0 \uplus \mathcal{X}_1$ with $|\mathcal{X}_0| = |\mathcal{X}_1| = \kappa$. Then, by the choice of d , for every $\delta < \theta$, there exist $x \in \mathcal{X}_0$ and $y \in \mathcal{X}_1$ such that $d(z) = \delta$ whenever $(x \triangle y) \subseteq z \subseteq (x \cup y)$. Clearly, x, y are distinct elements of \mathcal{X} .

(4) Similar to the proof of Clause (2). □

Proposition 3.3. *Suppose that $\lambda > \text{cf}(\lambda) = \kappa$ are infinite cardinals. Then for every cardinals θ, χ :*

- (1) $S(\kappa, \theta)$ entails $S(\lambda, \theta)$;
- (2) $S^*(\kappa, \theta, \chi)$ entails $S^*(\lambda, \theta, \chi)$, provided that $\mu^{<\chi} < \lambda$ for every cardinal $\mu < \lambda$.

Proof. Pick a club Λ in λ with $\text{otp}(\Lambda) = \kappa$, and derive a mapping $h : \lambda \rightarrow \kappa$ by stipulating $h(\alpha) := \text{otp}(\Lambda \cap \alpha)$.

(1) Let $d : [\kappa]^{<\omega} \rightarrow \theta$ be a witness to $S(\kappa, \theta)$. Define $d_h : [\lambda]^{<\omega} \rightarrow \theta$ by stipulating $d_h(z) := d(h[z])$.

To see that d_h witnesses $S(\lambda, \theta)$, suppose that we are given a λ -sized family $\mathcal{X} \subseteq [\lambda]^{<\omega}$, and a prescribed colour $\delta < \theta$. Put $\mathcal{X}_h := \{h[x] \mid x \in \mathcal{X}\}$. As $|\mu^{<\omega}| < \lambda = |\mathcal{X}|$ for all $\mu \in \Lambda$, we infer that \mathcal{X}_h is a κ -sized subfamily of $[\kappa]^{<\omega}$. Thus, by the choice of d , we may pick two distinct $x', y' \in \mathcal{X}_h$ such that $d(z') = \delta$ whenever $(x' \triangle y') \subseteq z' \subseteq (x' \cup y')$. Now, find $x, y \in \mathcal{X}$ such that $h[x] = x'$ and $h[y] = y'$. Clearly, x and y are distinct. Finally, suppose that z is some set satisfying $(x \triangle y) \subseteq z \subseteq (x \cup y)$. Then $(x' \triangle y') \subseteq h[z] \subseteq (x' \cup y')$, and hence $d_h(z) = d(h[z]) = \delta$, as sought.

(2) Let $d : [\kappa]^{<\chi} \rightarrow \theta$ be a witness to $S^*(\kappa, \theta, \chi)$. Define $d_h : [\lambda]^{<\chi} \rightarrow \theta$ by stipulating $d_h(z) := d(h[z])$. Note that for every λ -sized family $\mathcal{X} \subseteq [\lambda]^{<\chi}$, $\mathcal{X}_h := \{h[x] \mid x \in \mathcal{X}\}$ is a κ -sized subfamily of $[\kappa]^{<\chi}$, because $|\mu^{<\chi}| < \lambda = |\mathcal{X}|$ for all $\mu \in \Lambda$. The rest of the verification is similar to that of Clause (1). □

Recall that $\text{Pr}_1(\kappa, \kappa, \theta, \chi)$ asserts the existence of a colouring $c : [\kappa]^2 \rightarrow \theta$ satisfying that for every $\gamma < \theta$ and every $\mathcal{A} \subseteq [\kappa]^{<\chi}$ of size κ , consisting of pairwise disjoint sets, there exist $x, y \in \mathcal{A}$ with $\sup(x) < \min(y)$ for which $c[x \times y] = \{\gamma\}$.

Lemma 3.4. *Suppose that $\text{Pr}_1(\kappa, \kappa, \theta, \chi)$ holds for given infinite cardinals $\chi \leq \theta \leq \kappa = \text{cf}(\kappa)$.*

If κ is uncountable, and $\mu^{<\chi} < \kappa$ for every cardinal $\mu < \kappa$, then $S^(\kappa, \theta, \chi)$ holds.*

Proof. Let $c : [\kappa]^2 \rightarrow \theta$ be a witness to $\text{Pr}_1(\kappa, \kappa, \theta, \chi)$. Fix a bijection $\pi : \theta \leftrightarrow \theta \times \chi$. Define $c_0 : [\kappa]^2 \rightarrow \theta$ and $c_1 : [\kappa]^2 \rightarrow \chi$ in such a way that if $c(\alpha, \beta) = \gamma$ and $\pi(\gamma) = \langle \delta, \epsilon \rangle$, then $c_0(\alpha, \beta) = \delta$ and $c_1(\alpha, \beta) = \epsilon$.

Now, define $d : [\kappa]^{<\chi} \rightarrow \theta$ as follows. Let $z \in [\kappa]^{<\chi}$ be arbitrary. If $M_z := \{\langle \alpha, \beta \rangle \in [z]^2 \mid c_1(\alpha, \beta) = \sup(c_1 \text{ "}[z]^2)\}$ is nonempty, then let $d(z) := c_0(\alpha, \beta)$ for an arbitrary choice of $\langle \alpha, \beta \rangle$ from M_z . Otherwise, let $d(z) := 0$.

To see that d works, suppose we are given a sequence $\langle \mathcal{X}_i \mid i < n \rangle \in \prod_{i < n} [[\kappa]^{<\chi}]^\kappa$, for some integer $n \geq 2$, along with some prescribed colour $\delta < \theta$.

By thinning-out, we may assume that for all $i < n$, \mathcal{X}_i forms a Δ -system with root, say, r_i .¹² In particular, for all $i < n$, $\{x \setminus r_i \mid x \in \mathcal{X}_i\}$ consists of κ many pairwise disjoint bounded subsets of κ . Consequently, we can construct (e.g., by recursion on $\gamma < \kappa$) a matrix $\langle x_i^\gamma \mid \gamma < \kappa, i < n \rangle$ in such a way that for all $\gamma < \gamma' < \kappa$ and $i < j < n$:

- $r_i \uplus x_i^\gamma \in \mathcal{X}_i$;
- $\sup(r_0 \cup \dots \cup r_{n-1}) < \min(x_i^\gamma) \leq \sup(x_i^\gamma) < \min(x_j^\gamma) \leq \sup(x_j^\gamma) < \min(x_j^{\gamma'})$.

By the pigeonhole principle, let us fix $\Gamma \in [\kappa]^\kappa$ and $\epsilon < \chi$ such that for all $\gamma \in \Gamma$:

- $\sup(c_1[r_0 \cup \dots \cup r_{n-1} \cup x_0^\gamma \cup \dots \cup x_{n-1}^\gamma]^2) = \epsilon$.

Denote $a_\gamma := x_0^\gamma \uplus \dots \uplus x_{n-1}^\gamma$. As $\mathcal{A} := \{a_\gamma \mid \gamma \in \Gamma\}$ is a κ -sized subfamily of $[\kappa]^{<\chi}$ consisting of pairwise disjoint sets, we may now pick $\gamma < \gamma'$ both from Γ for which $c[a_\gamma \times a_{\gamma'}] = \{\pi^{-1}\langle \delta, \epsilon + 1 \rangle\}$.

Write $\bar{x}_0 := r_0 \uplus x_0^\gamma$, and for all nonzero $i < n$, write $\bar{x}_i := r_i \uplus x_i^{\gamma'}$. Clearly, $\langle \bar{x}_i \mid i < n \rangle \in \prod_{i < n} \mathcal{X}_i$, and $\langle \sup(\bar{x}_i) \mid i < n \rangle$ is strictly increasing. Next, suppose that we are given z satisfying

$$\bigcup_{i < n} \left(\bar{x}_i \setminus \bigcup_{j \in n \setminus \{i\}} \bar{x}_j \right) \subseteq z \subseteq \bigcup_{i < n} \bar{x}_i.$$

Claim 3.4.1. M_z is a nonempty subset of $a_\gamma \times a_{\gamma'}$.

Proof. Let $\langle \alpha, \beta \rangle \in [z]^2$ be arbitrary. As $\bigcup_{i < n} \bar{x}_i = (\bigcup_{i < n} r_i) \uplus x_0^\gamma \uplus (\biguplus_{0 < i < n} x_i^{\gamma'})$, we consider the following cases:

- (1) Suppose that $\alpha \in (\bigcup_{i < n} r_i)$.

By $\beta \in (r_0 \cup \dots \cup r_{n-1} \cup x_0^\gamma \cup x_1^{\gamma'} \cup \dots \cup x_{n-1}^{\gamma'})$, we have $c_1(\alpha, \beta) \leq \epsilon$.

- (2) Suppose that $\alpha \in x_0^\gamma$.

(a) If $\beta \in (r_0 \cup \dots \cup r_{n-1} \cup x_0^\gamma)$, then $c_1(\alpha, \beta) \leq \epsilon$;

(b) If $\beta \in \biguplus_{0 < i < n} x_i^{\gamma'}$, then $\langle \alpha, \beta \rangle \in a_\gamma \times a_{\gamma'}$ and hence $c(\alpha, \beta) = \pi^{-1}\langle \delta, \epsilon + 1 \rangle$, so that $c_1(\alpha, \beta) = \epsilon + 1$.

- (3) Suppose that $\alpha \in \biguplus_{0 < i < n} x_i^{\gamma'}$.

(a) If $\beta \in x_0^\gamma$, then $\alpha > \beta$ which gives a contradiction to $\langle \alpha, \beta \rangle \in [z]^2$;

(b) If $\beta \in r_0 \cup \dots \cup r_{n-1} \cup x_1^{\gamma'} \cup \dots \cup x_{n-1}^{\gamma'}$, then $c_1(\alpha, \beta) \leq \epsilon$.

Finally, by

$$z \supseteq \bigcup_{i < n} \left(\bar{x}_i \setminus \bigcup_{j \in n \setminus \{i\}} \bar{x}_j \right) \supseteq \left(\bigcup_{i < n} \bar{x}_i \setminus \bigcup_{i < n} r_i \right),$$

we have $x_0^\gamma \times x_1^{\gamma'} \subseteq [z]^2$, so that case (2)(b) is indeed feasible. Consequently, M_z is a nonempty subset of $a_i \times a_j$. \square

Let $\langle \alpha, \beta \rangle \in M_z$ be such that $d(z) = c_0(\alpha, \beta)$. By the preceding claim, $c(\alpha, \beta) = \pi^{-1}\langle \delta, \epsilon + 1 \rangle$, so that $d(z) = c_0(\alpha, \beta) = \delta$, as sought. \square

The colouring principle $\text{Pr}_1(\dots)$ was studied extensively by many authors, including Eisworth, Galvin, Rinot, Shelah, and Todorćević. To mention a few results:

Fact 3.5. Suppose that κ is a regular uncountable cardinal.

Then $\text{Pr}_1(\kappa, \kappa, \theta, \chi)$ holds in all of the following cases:

- (1) $\kappa = \theta = \mathfrak{b} = \omega_1$ and $\chi = \omega$;
- (2) $\kappa = \theta > \chi^+$, and $\square(\kappa)$ holds;¹³

¹²This is where we use the hypothesis that $\mu^{<\chi} < \kappa$ for every cardinal $\mu < \kappa$.

¹³The definition of $\square(\kappa)$ may be found in [33, p. 267].

- (3) $\kappa = \theta > \chi^+$, and $E_{\geq \chi}^\kappa$ admits a non-reflecting stationary set;
- (4) $\kappa = \theta = \lambda^+ > \chi^+$, and λ is regular;
- (5) $\kappa = \theta = \lambda^+$, λ is singular, $\chi = \text{cf}(\lambda)$, and $\text{pp}(\lambda) = \lambda^+$ (e.g., $\lambda^{\text{cf}(\lambda)} = \lambda^+$);¹⁴
- (6) $\kappa = \theta = \lambda^+$, λ is singular, $\chi = \text{cf}(\lambda)$, and there exists a collection of $< \text{cf}(\lambda)$ many stationary subsets of κ that do not reflect simultaneously;
- (7) $\kappa = \lambda^+$, λ is singular, and $\theta = \chi = \text{cf}(\lambda)$.

Proof. (1) By Lemma 1.0 of [34, §1].

(2) By Theorem B of [24].

(3) By Corollary 3.2 of [25].

(4) By Clause (3) above.

(5) By Corollary 6.2 of [4].

(6) By Corollary 3.3 of [23].

(7) By Conclusion 4.1 of [28]. □

It follows that $S^*(\lambda^+, \lambda^+, \omega)$ holds for every regular cardinal $\lambda \geq \omega_1$. Now, what about $S^*(\omega_1, \omega_1, \omega)$?

► Galvin proved [9] that the failure of $\text{Pr}_1(\omega_1, \omega_1, \omega_1, \omega)$ is consistent with ZFC, and hence Lemma 3.4 is inapplicable here.

► Getting just $S(\omega_1, \omega_1)$ turns out to be ready-made; It follows from Theorem 2.6 of [25] that $S(\mu^+, \mu^+)$ holds for every infinite cardinal μ satisfying $\mu^{<\mu} = \mu$.

Altogether, there is a need for a dedicated proof of $S^*(\omega_1, \omega_1, \omega)$. This is our next task.

Theorem 3.6. $S^*(\omega_1, \omega_1, \omega)$ holds.

Proof. As the product of \mathfrak{c} many separable topological spaces is again separable, let us pick a countable dense subset $\{f_\iota \mid \iota < \omega\}$ of the product space ω^{ω_1} . Notice that this means that for every finite subset $a \subseteq \omega_1$ and every function $f : a \rightarrow \omega$, there exists some $\iota < \omega$ such that $f_\iota \upharpoonright a = f$.

Next, by Theorem 1.5 of [20], let us pick a function $\text{osc} : [\omega_1]^2 \rightarrow \omega$ satisfying that for every positive integers k, l , every uncountable families $\mathcal{A} \subseteq [\omega_1]^k$ and $\mathcal{B} \subseteq [\omega_1]^l$, each consisting of pairwise disjoint sets, and every $s < \omega$, there exist $a \in \mathcal{A}$ and a sequence $\langle b_m \mid m < s \rangle$ of elements in \mathcal{B} such that for all $m < s$:

- $\max(a) < \min(b_m)$, and
- $\text{osc}(a(i), b_m(j)) = \text{osc}(a(i), b_0(j)) + m$ for all $i < k$ and $j < l$.¹⁵

For every nonzero $\alpha < \omega_1$, fix a surjection $\psi_\alpha : \omega \rightarrow \alpha$. Finally, define the function $d : [\omega_1]^{<\omega} \rightarrow \omega_1$ as follows. Let $z \in [\omega_1]^{<\omega}$ be arbitrary. If $M_z := \{\langle \alpha, \beta \rangle \in [z]^2 \mid \text{osc}(\alpha, \beta) = \sup(\text{osc}([z]^2))\}$ is empty, then let $d(z) := \emptyset$. Otherwise, pick an arbitrary $\langle \alpha, \beta \rangle$ from M_z , let ι be the maximal natural number to satisfy that 2^ι divides $\text{osc}(\alpha, \beta)$, and then put $d(z) := \psi_\alpha(f_\iota(\alpha))$.

To see that d works, suppose we are given a sequence $\langle \mathcal{X}_i \mid i < n \rangle \in \prod_{i < n} [[\omega_1]^{<\omega}]^{\omega_1}$, for some integer $n \geq 2$, along with some prescribed colour $\delta < \omega_1$. As in the proof of Lemma 3.4, we may find a matrix $\langle x_i^\gamma \mid \gamma < \omega_1, i < n \rangle$ and a sequence $\langle r_i \mid i < n \rangle$ such that for all $\gamma < \gamma' < \omega_1$ and $i < j < n$:

- $r_i \uplus x_i^\gamma \in \mathcal{X}_i$;
- $\sup(r_0 \cup \dots \cup r_{n-1}) < \min(x_i^\gamma) \leq \max(x_i^\gamma) < \min(x_j^\gamma) \leq \max(x_j^\gamma) < \min(x_0^{\gamma'})$.

For all $\gamma < \omega_1$, denote $a^\gamma := x_0^\gamma$ and $b^\gamma := x_1^\gamma \uplus \dots \uplus x_{n-1}^\gamma$. By the pigeonhole principle, let us fix an uncountable $\Gamma \subseteq \omega_1$ along with $k, l, \iota, \epsilon < \omega$ such that for all $\gamma \in \Gamma$:

- $|a^\gamma| = k$ and $|b^\gamma| = l$;
- $\psi_\alpha(f_\iota(\alpha)) = \delta$ for all $\alpha \in a^\gamma$;
- $\max(\text{osc}([r_0 \cup \dots \cup r_{n-1} \cup a^\gamma \cup b^\gamma]^2)) = \epsilon$.

Put $s := \epsilon + 1 + 2^\iota + 1$. Consider $\mathcal{A} := \{a^\gamma \mid \gamma \in \Gamma\}$ and $\mathcal{B} := \{b^\gamma \mid \gamma \in \Gamma\}$. As $\mathcal{A} \subseteq [\omega_1]^k$ and $\mathcal{B} \subseteq [\omega_1]^l$ are uncountable families, each consisting of pairwise disjoint sets, we may pick $a \in \mathcal{A}$ and a sequence $\langle b_m \mid m < s \rangle$ of elements in \mathcal{B} such that for all $m < s$:

¹⁴For a light introduction to $\text{pp}(\lambda)$, see [22].

¹⁵Here, $a(i)$ stands for the unique $\alpha \in a$ to satisfy $|a \cap \alpha| = i$. The interpretation of $b_m(j)$ is similar.

- $\max(a) < \min(b_m)$, and
- $\text{osc}(a(i), b_m(j)) = \text{osc}(a(i), b_0(j)) + m$ for all $i < k$ and $j < l$.

Write $\mathbf{m} := \max(\text{osc}([a \times b_0]))$. Let t be the unique natural number to satisfy $0 \leq t < 2^\iota$ and $\mathbf{m} + \epsilon + 1 \equiv t \pmod{2^\iota}$. Put $m := \epsilon + 1 + 2^\iota - t$. Then $m < s$ and ι is the maximal natural number to satisfy that 2^ι divides $\mathbf{m} + m$.

Fix $\gamma < \gamma' < \omega_1$ such that $a = a^\gamma$ and $b_m = b^{\gamma'}$. Write $\bar{x}_0 := r_0 \uplus x_0^\gamma$, and for all nonzero $i < n$, write $\bar{x}_i := r_i \uplus x_i^{\gamma'}$. Clearly, $\langle \bar{x}_i \mid i < n \rangle \in \prod_{i < n} \mathcal{X}_i$, and $\langle \sup(\bar{x}_i) \mid i < n \rangle$ is strictly increasing. Next, suppose that we are given z satisfying

$$\bigcup_{i < n} \left(\bar{x}_i \setminus \bigcup_{j \in n \setminus \{i\}} \bar{x}_j \right) \subseteq z \subseteq \bigcup_{i < n} \bar{x}_i.$$

Claim 3.6.1. M_z is a nonempty subset of $a \times b_m$, and $\text{osc}(\alpha, \beta) = \mathbf{m} + m$ for all $\langle \alpha, \beta \rangle \in M_z$.

Proof. Let $\langle \alpha, \beta \rangle \in [z]^2$ be arbitrary. As $\bigcup_{i < n} \bar{x}_i = (\bigcup_{i < n} r_i) \uplus a^\gamma \uplus b^{\gamma'}$, we consider the following cases:

- (1) Suppose that $\alpha \in (\bigcup_{i < n} r_i)$.
By $\beta \in (r_0 \cup \dots \cup r_{n-1} \cup a^\gamma \cup b^{\gamma'})$, we have $\text{osc}(\alpha, \beta) \leq \epsilon$.
- (2) Suppose that $\alpha \in a^\gamma$.
(a) If $\beta \in (r_0 \cup \dots \cup r_{n-1} \cup a^\gamma)$, then $\text{osc}(\alpha, \beta) \leq \epsilon$;
(b) If $\beta \in b^{\gamma'}$, then $\langle \alpha, \beta \rangle \in a \times b_m$, so that writing $i := a \cap \alpha$ and $j := b_m \cap \beta$, we have $\text{osc}(\alpha, \beta) = \text{osc}(a(i), b_m(j)) = \text{osc}(a(i), b_0(j)) + m \geq m > \epsilon$.
- (3) Suppose that $\alpha \in b^{\gamma'}$.
(a) If $\beta \in a^\gamma$, then $\alpha > \beta$ which gives a contradiction to $\langle \alpha, \beta \rangle \in [z]^2$;
(b) If $\beta \in r_0 \cup \dots \cup r_{n-1} \cup b^{\gamma'}$, then $\text{osc}(\alpha, \beta) \leq \epsilon$.

Finally, by

$$z \supseteq \bigcup_{i < n} \left(\bar{x}_i \setminus \bigcup_{j \in n \setminus \{i\}} \bar{x}_j \right) \supseteq \left(\bigcup_{i < n} \bar{x}_i \setminus \bigcup_{i < n} r_i \right),$$

we have $a^\gamma \times b^{\gamma'} \subseteq [z]^2$, so that case (2)(b) is indeed feasible, and M_z is a nonempty subset of $a^\gamma \times b^{\gamma'} = a \times b_m$. It follows that $M_z = \{ \langle \alpha, \beta \rangle \in a \times b_m \mid \text{osc}(\alpha, \beta) = \mathbf{m} + m \}$. \square

Let $\langle \alpha, \beta \rangle \in M_z$ be arbitrary. By the choice of m , we know that ι is the maximal natural number to satisfy that 2^ι divides $\mathbf{m} + m$, and hence $d(z) = \psi_\alpha(f_\iota(\alpha)) = \delta$, as sought. \square

Corollary 3.7. Suppose that κ is a regular uncountable cardinal that admits a nonreflecting stationary set (e.g., κ is the successor of an infinite regular cardinal). Then:

- $S^*(\kappa, \kappa, \omega)$ holds. In particular:
- There exists a colouring $d : [\kappa]^{<\omega} \rightarrow \kappa$ such that for every $\mathcal{X} \subseteq [\kappa]^{<\omega}$ of size κ and every colour $\delta < \kappa$, there exist two distinct $x, y \in \mathcal{X}$ satisfying $d(x \cup y) = \delta$.

Proof. For $\kappa = \aleph_1$, use Theorem 3.6. For $\kappa > \aleph_1$, use Lemma 3.4 together with Fact 3.5(3). \square

Note that the second bullet of the preceding generalizes the celebrated result from [33, p. 285] asserting that $\kappa \not\rightarrow [\kappa]_\kappa^2$ holds for every regular uncountable cardinal κ that admits a nonreflecting stationary set.

As colouring of the real line is of a special interest, and as the results so far only shed a limited amount of light on cardinals of the form 2^λ , our next task is proving the following.

Theorem 3.8. Suppose that λ is an infinite cardinal satisfying $2^{<\lambda} = \lambda$. Then $S(\text{cf}(2^\lambda), \omega)$ holds.

Proof. By $2^{<\lambda} = \lambda$ and a classic theorem of Sierpiński, there exists a linear ordering of size 2^λ with a dense subset of size λ . Then, by Theorem 3 of [32] (independently, also by the main result of [3]), we may fix a linear order (L, \triangleleft) of size $\kappa := \text{cf}(2^\lambda)$ which is κ -entangled. The latter means that for every $\mu < \omega$, every

$\Omega \subseteq \mu$, and every injective sequence $\langle f_\alpha : \mu \rightarrow L \mid \alpha < \kappa \rangle$ of order-preserving maps from (μ, \in) to (L, \triangleleft) , with pairwise disjoint images, there exist $\alpha < \beta < \kappa$ such that for all $\iota < \mu$: $f_\alpha(\iota) \triangleleft f_\beta(\iota)$ iff $\iota \in \Omega$.¹⁶

Fix a sequence of injections $\langle l_\alpha : \omega \rightarrow L \mid \alpha < \kappa \rangle$ such that $\text{Im}(l_\alpha) \cap \text{Im}(l_\beta) = \emptyset$ for all $\alpha < \beta < \kappa$. Define a colouring $c : [\kappa]^2 \rightarrow \omega$ as follows. For all $\alpha < \beta < \kappa$, if there exists some $\tau < \omega$ such that $l_\alpha(\tau) \triangleleft l_\beta(\tau)$, let $c(\alpha, \beta)$ be the least such τ . Otherwise, let $c(\alpha, \beta) := 0$.

By $\kappa \leq 2^\lambda$, let $\langle g_\alpha : \lambda \rightarrow 2 \mid \alpha < \kappa \rangle$ be a sequence of pairwise distinct functions. For all $\alpha < \beta < \kappa$, let $\Delta(\alpha, \beta) := \min\{\varepsilon < \lambda \mid g_\alpha(\varepsilon) \neq g_\beta(\varepsilon)\}$. Now, to define $d : [\kappa]^{<\omega} \rightarrow \omega$, let $z \in [\kappa]^{<\omega}$ be arbitrary. If $M_z := \{\langle \alpha, \beta \rangle \in [z]^2 \mid \Delta(\alpha, \beta) = \sup(\Delta''[z]^2)\}$ is nonempty, then let $d(z) := c(\alpha, \beta)$ for an arbitrary choice of $\langle \alpha, \beta \rangle$ from M_z . Otherwise, let $d(z) := 0$.

To see that d witnesses $S(\kappa, \omega)$, suppose that we are given a κ -sized family $\mathcal{X} \subseteq [\kappa]^{<\omega}$ and a prescribed colour $\delta < \omega$. By the Δ -system lemma, we may find a sequence $\langle a_\gamma \mid \gamma < \kappa \rangle$ along with $r \in [\kappa]^{<\omega}$ and $m < \omega$ such that for all $\gamma < \gamma' < \kappa$:

- $|a_\gamma| = m$;
- $r \uplus a_\gamma \in \mathcal{X}$;
- $\sup(r) < \min(a_\gamma) \leq \max(a_\gamma) < \min(a_{\gamma'})$.

For each $\gamma < \kappa$, let $f_\gamma : m(\delta + 1) \rightarrow L$ denote the unique order-preserving map from $(m(\delta + 1), \in)$ to (L, \triangleleft) such that $\text{Im}(f_\gamma) = \{l_\alpha(\tau) \mid \alpha \in a_\gamma, \tau \leq \delta\}$. Also, fix some enumeration $\{a_\gamma(j) \mid j < m\}$ of a_γ .

Next, by an iterated application of the pigeonhole principle, let us fix $\Gamma \in [\kappa]^\kappa$ together with $\epsilon < \lambda$, $t : m \rightarrow {}^{(\epsilon+1)}2$ and $h : m \times (\delta + 1) \leftrightarrow m(\delta + 1)$ such that for all $\gamma \in \Gamma$:

- $\max(\Delta''[r \uplus a_\gamma]^2) = \epsilon$;
- $\langle g_{a_\gamma(j)} \upharpoonright (\epsilon + 1) \mid j < m \rangle = t$;¹⁷
- $f_\gamma(h(j, \tau)) = l_{a_\gamma(j)}(\tau)$ for all $j < m$ and $\tau \leq \delta$.

Put $\Omega := h[m \times \{\delta\}]$. As (L, \triangleleft) is κ -entangled, let us pick $\gamma < \gamma'$ both from Γ such that for all $\iota < m(\delta + 1)$: $f_\gamma(\iota) \triangleleft f_{\gamma'}(\iota)$ iff $\iota \in \Omega$. Write $x := r \uplus a_\gamma$ and $y := r \uplus a_{\gamma'}$. Clearly, x, y are two distinct elements of \mathcal{X} . Next, suppose that we are given z satisfying $x \triangleleft y \subseteq z \subseteq x \cup y$.

Claim 3.8.1. M_z is a nonempty subset of $\{\langle a_\gamma(j), a_{\gamma'}(j) \rangle \mid j < m\}$.

Proof. Let $\langle \alpha, \beta \rangle \in [z]^2$ be arbitrary. As $x \cup y = r \uplus a_\gamma \uplus a_{\gamma'}$, we consider the following cases:

(1) Suppose that $\alpha \in r$.

By $\beta \in r \uplus a_\gamma \uplus a_{\gamma'}$, we have $\Delta(\alpha, \beta) \leq \epsilon$.

(2) Suppose that $\alpha \in a_\gamma$.

(a) If $\beta \in (r \uplus a_\gamma)$, then $\Delta(\alpha, \beta) \leq \epsilon$;

(b) If $\beta \in a_{\gamma'}$, then let $j_\alpha, j_\beta < m$ be such that $\alpha = a_\gamma(j_\alpha)$ and $\beta = a_{\gamma'}(j_\beta)$. There are two cases to consider:

(i) If $j_\alpha = j_\beta$, then $g_\alpha \upharpoonright (\epsilon + 1) = g_{a_\gamma(j_\alpha)} \upharpoonright (\epsilon + 1) = t(j_\alpha) = t(j_\beta) = g_{a_{\gamma'}(j_\beta)} \upharpoonright (\epsilon + 1) = g_\beta \upharpoonright (\epsilon + 1)$, so that $\Delta(\alpha, \beta) > \epsilon$;

(ii) If $j_\alpha \neq j_\beta$, then $g_\alpha \upharpoonright (\epsilon + 1) = t(j_\alpha) = g_{a_{\gamma'}(j_\alpha)} \upharpoonright (\epsilon + 1)$, and hence

$$\Delta(\alpha, a_{\gamma'}(j_\alpha)) > \epsilon = \max(\Delta''[a_{\gamma'}]^2) \geq \Delta(a_{\gamma'}(j_\alpha), \beta),$$

so that $\Delta(\alpha, \beta) \leq \epsilon$.

(3) Suppose that $\alpha \in a_{\gamma'}$.

(a) If $\beta \in a_\gamma$, then $\alpha > \beta$ which gives a contradiction to $\langle \alpha, \beta \rangle \in [z]^2$;

(b) If $\beta \in r \uplus a_{\gamma'}$, then $\Delta(\alpha, \beta) \leq \epsilon$.

Finally, by $z \supseteq (x \triangleleft y) = a_\gamma \uplus a_{\gamma'}$, we have $a_\gamma \times a_{\gamma'} \subseteq [z]^2$, so that case (2)(b)(i) is indeed feasible. \square

As $\Omega = h[m \times \{\delta\}]$, we have $f_\gamma(\iota) \triangleleft f_{\gamma'}(\iota)$ iff $\iota \in h[m \times \{\delta\}]$. Let $j < m$ be such that $d(z) = c(a_\gamma(j), a_{\gamma'}(j))$. Then, for all $\tau \leq \delta$: $f_\gamma(h(j, \tau)) \triangleleft f_{\gamma'}(h(j, \tau))$ iff $h(j, \tau) \in h[m \times \{\delta\}]$ iff $\tau = \delta$. That is, for all $\tau \leq \delta$:

¹⁶Note that the definition of a (κ, μ) -entangled ordering in [32] only guarantees “ $\alpha \neq \beta$ ”, however, “ $\alpha < \beta$ ” can be ensured by appealing to the $(\kappa, 2\mu)$ -entangledness of the ordering.

¹⁷Note that $|{}^m({}^{(\epsilon+1)}2)| \leq 2^{<\lambda} = \lambda < \kappa$.

$l_{a_\gamma(j)}(\tau) \triangleleft l_{a_{\gamma'}(j)}(\tau)$ iff $\tau = \delta$. Recalling the definition of c , we altogether infer that $d(z) = c(a_\gamma(j), a_{\gamma'}(j)) = \delta$, as sought. \square

Corollary 3.9. *For every successor ordinal α :*

- (1) $S(\beth_\alpha, \omega)$ and $S^*(\aleph_\alpha, \text{cf}(\aleph_{\alpha-1}), \omega)$ hold,¹⁸
- (2) if $\beth_\alpha = \aleph_\alpha$, then $S^*(\aleph_\alpha, \aleph_\alpha, \omega)$ holds.¹⁹

For every limit ordinal α :

- (3) if $\text{cf}(\alpha)$ is uncountable and admitting a nonreflecting stationary set, then $S^*(\aleph_\alpha, \text{cf}(\alpha), \omega)$ holds;
- (4) if $\text{cf}(\alpha)$ is a successor of an infinite cardinal of cofinality θ , then $S^*(\aleph_\alpha, \theta, \omega)$ holds.

Proof. (1) Suppose that $\alpha = \beta + 1$.

Then $\lambda := \beth_\beta$ is a strong limit cardinal, and hence $2^{<\lambda} = \lambda$. So, by Theorem 3.8, $S(\text{cf}(2^\lambda), \omega)$ holds. But, then, by Proposition 3.3, $S(2^\lambda, \omega)$ holds. That is, $S(\beth_\alpha, \omega)$ holds.

As for the second part of Clause (1):

► If \aleph_β is a regular cardinal, then by Corollary 3.7, $S^*(\aleph_\alpha, \aleph_\alpha, \omega)$ holds.

► If \aleph_β is a singular cardinal, then by Fact 3.5(7), $\text{Pr}_1(\aleph_\alpha, \aleph_\alpha, \text{cf}(\aleph_\beta), \text{cf}(\aleph_\beta))$ holds. Then, by Lemma 3.4, $S^*(\aleph_\alpha, \text{cf}(\aleph_\beta), \omega)$ holds.

- (2) Suppose that $\alpha = \beta + 1$ and $\beth_\alpha = \aleph_\alpha$. Write $\lambda := \aleph_\beta$.

► If λ is a regular cardinal, then by Corollary 3.7, $S^*(\aleph_\alpha, \aleph_\alpha, \omega)$ holds.

► If λ is a singular cardinal, then $\text{pp}(\lambda) \leq 2^\lambda = 2^{\aleph_\beta} \leq 2^{\beth_\beta} = \beth_\alpha = \aleph_\alpha = \lambda^+$, and then by Fact 3.5(5), $\text{Pr}_1(\lambda^+, \lambda^+, \lambda^+, \text{cf}(\lambda))$ holds. So, by Lemma 3.4, $S^*(\aleph_\alpha, \aleph_\alpha, \omega)$ holds.

- (3) Suppose that $\text{cf}(\alpha) = \kappa$, where κ is an uncountable cardinal admitting a nonreflecting stationary set. By Fact 3.5(3), $\text{Pr}_1(\kappa, \kappa, \kappa, \omega)$ holds. Then, by Lemma 3.4, $S^*(\aleph_\alpha, \aleph_\alpha, \omega)$ holds. As $\text{cf}(\aleph_\alpha) = \text{cf}(\alpha) = \kappa$, we infer from Proposition 3.3 that $S^*(\aleph_\alpha, \text{cf}(\alpha), \omega)$ holds.

- (4) Suppose that $\text{cf}(\alpha) = \mu^+$ for some infinite cardinal μ of cofinality, say, θ . Given Clause (3), we may assume that μ is singular. By Fact 3.5(7), $\text{Pr}_1(\mu^+, \mu^+, \theta, \theta)$ holds. Then, by Lemma 3.4, $S^*(\mu^+, \theta, \omega)$ holds. As $\text{cf}(\aleph_\alpha) = \text{cf}(\alpha) = \mu^+$, we infer from Proposition 3.3 that $S^*(\aleph_\alpha, \theta, \omega)$ holds. \square

Corollary 3.10. *For every ordinal α such that $\text{cf}(\alpha)$ is a successor cardinal, $S(\beth_\alpha, \omega)$ holds.*

Proof. By Corollary 3.9 and Proposition 3.2. \square

Remarks. i. The restriction to cofinality of a successor cardinal is necessary, as it follows from Proposition 3.2(4) that $S(\beth_\alpha, \omega)$ fails for any ordinal α satisfying $\alpha \rightarrow [\alpha]_2^2$.

- ii. It is unknown whether the conclusion $S(\beth_\alpha, \omega)$ may be replaced by the stronger conclusion $S^*(\beth_\alpha, \omega, \omega)$. In fact, already whether ZFC implies $\beth_1 \nrightarrow [\beth_1; \beth_1]_2^2$ is a longstanding open problem.

4. COLOURINGS FOR SUMSETS AND BOUNDED FINITE SUMS

The main goal of this section is to show that for unboundedly many regular uncountable cardinals κ , if $|G| = \kappa$ then $G \nrightarrow [\kappa]_\kappa^{\text{FS}_2}$ and even $G \nrightarrow [\kappa]_\kappa^{\text{SuS}}$. A minor goal is to prove some no-go theorems.

4.1. Sumsets. We commence with a lemma that will simplify some reasoning concerning sumsets.

Lemma 4.1. *Let G be a commutative cancellative semigroup of cardinality $\kappa > \omega$, let $\theta \leq \kappa$ be an arbitrary cardinal, and let $c : G \rightarrow \theta$ be some colouring. Then for each $\delta < \theta$, the following two conditions are equivalent:*

- (1) *For every $X, Y \subseteq G$ with $|X| = |Y| = \kappa$, we have $\delta \in c[X + Y]$ (that is, there are $x \in X$ and $y \in Y$ such that $c(x + y) = \delta$).*
- (2) *For every integer $n \geq 2$ and κ -sized sets $X_1, \dots, X_n \subseteq G$, we have $\delta \in c[X_1 + \dots + X_n]$ (that is, there are $x_1 \in X_1, \dots, x_n \in X_n$ such that $c(x_1 + \dots + x_n) = \delta$).*

¹⁸Note that if $\aleph_{\alpha-1}$ is regular, then $S^*(\aleph_\alpha, \text{cf}(\aleph_{\alpha-1}), \omega)$ is equivalent to $S^*(\aleph_\alpha, \aleph_\alpha, \omega)$.

¹⁹Note that GCH is equivalent to the assertion that $\beth_\alpha = \aleph_\alpha$ for all ordinals α , and that if ZFC is consistent then so is ZFC + GCH + every regular uncountable cardinal is of the form \aleph_α for some successor ordinal α .

Proof. We focus on the nontrivial implication $1 \implies 2$.

Proceed by induction on $n \in \{2, 3, \dots\}$. Suppose the statement holds true for a given n , and suppose we are given κ -sized sets X_1, \dots, X_n, X_{n+1} . First, notice that $X_1 + \dots + X_n$ has cardinality κ (since the elements $x_1 + \dots + x_{n-1} + y$, where the $x_i \in X_i$ are fixed, and y ranges over X_n , are all distinct by cancellativity). Thus, by our assumption we can find $x_1 + \dots + x_n \in X_1 + \dots + X_n$ and $x_{n+1} \in X_{n+1}$ such that $c(x_1 + \dots + x_n + x_{n+1}) = c((x_1 + \dots + x_n) + x_{n+1}) = \delta$. \square

Theorem 4.2. *Suppose that G is commutative cancellative semigroup of cardinality, say, κ .*

If $S^(\kappa, \theta, \omega)$ holds, then so does $G \rightarrow [\kappa]_\theta^{\text{SuS}}$.*

Proof. Let $d : [\kappa]^{<\omega} \rightarrow \theta$ be a witness to $S^*(\kappa, \theta, \omega)$. Using Lemma 2.2, embed G into a direct sum $\bigoplus_{\alpha < \kappa} G_\alpha$, with each G_α a countable abelian group. Then, define $c : G \rightarrow \theta$ by stipulating:

$$c(x) := d(\text{supp}(x)).$$

While the axiom $S^*(\kappa, \theta, \omega)$ allows to handle any finite number of κ -sized families, we shall take advantage of Lemma 4.1 that reduces the algebraic problem into looking at sumsets of 2 sets.

Thus, let X and Y be two κ -sized subsets of G , and let $\delta < \theta$ be arbitrary. Since each $x \in G$ has a finite support, and each of the G_α are countable, there are only countably many elements of G with a given support. Therefore, both $\mathcal{X} := \{\text{supp}(x) \mid x \in X\}$ and $\mathcal{Y} := \{\text{supp}(y) \mid y \in Y\}$ are κ -sized subfamilies of $[\kappa]^{<\omega}$. Now, as d witnesses $S^*(\kappa, \theta, \omega)$, we may pick $\langle x, y \rangle \in X \times Y$ such that $d(z) = \delta$ whenever

$$\text{supp}(x) \triangle \text{supp}(y) \subseteq z \subseteq \text{supp}(x) \cup \text{supp}(y),$$

in particular $z := \text{supp}(x + y)$ satisfies the above equation by Proposition 2.4, and hence $c(x + y) = d(z) = \delta$. \square

Corollary 4.3. *Let G be any commutative cancellative semigroup of cardinality, say, λ .*

If $\kappa := \text{cf}(\lambda)$ is an uncountable cardinal satisfying at least one of the following conditions:

- (1) $\square(\kappa)$ holds;
- (2) κ admits a non-reflecting stationary set (e.g., $\kappa = \mu^+$ for μ regular);
- (3) $\kappa = \mu^+$, μ is singular, and $\text{pp}(\mu) = \mu^+$ (e.g., $\mu^{\text{cf}(\mu)} = \mu^+$),

then $G \rightarrow [\lambda]_\kappa^{\text{SuS}}$ holds.

Proof. By Lemma 3.4, Fact 3.5 and Theorem 3.6, any of the above hypotheses imply that $S^*(\kappa, \kappa, \omega)$ holds. Then by Proposition 3.3, $S^*(\lambda, \kappa, \omega)$ holds, as well. Now, appeal to Theorem 4.2. \square

Corollary 4.4. *It is consistent with ZFC that for every infinite commutative cancellative semigroup G , letting $\kappa := |G|$, $G \rightarrow [\kappa]_{\text{cf}(\kappa)}^{\text{SuS}}$ holds iff $\text{cf}(\kappa) > \omega$.*

Proof. If there exists a weakly compact cardinal in Gödel's constructible universe L , then let μ denote the least such one and work in L_μ . Otherwise, work in L . In both cases, we end up with a model of ZFC in which $\square(\kappa)$ holds for every regular uncountable cardinal κ [16, Theorem 6.1], and in which every singular cardinal is a strong limit [11]. Now, there are three cases to consider:

- If $\text{cf}(\kappa) > \omega$, then $\square(\text{cf}(\kappa))$ holds and then $G \rightarrow [\kappa]_{\text{cf}(\kappa)}^{\text{SuS}}$ holds as a consequence of Corollary 4.3.
- If $\kappa > \text{cf}(\kappa) = \omega$ and $G \rightarrow [\kappa]_{\text{cf}(\kappa)}^{\text{SuS}}$ holds, then so does $G \rightarrow [\kappa]_\omega^{\text{FS}_2}$. But then by Proposition 4.10 below, $\kappa \rightarrow [\kappa]_\omega^2$ holds, contradicting Theorem 54.1 of [5] and the fact that κ is a strong limit.
- If $\kappa = \omega$ and $G \rightarrow [\kappa]_{\text{cf}(\kappa)}^{\text{SuS}}$ holds, then so does $G \rightarrow [\omega]_2^{\text{FS}}$, contradicting Hindman's theorem. \square

We conclude this subsection with an analogue of Corollary 2.8 in the context of sumsets:

Corollary 4.5. *For every infinite cardinal λ , and every cardinal θ , the following are equivalent:*

- (1) $\lambda^+ \rightarrow [\lambda^+]_\theta^2$ holds;
- (2) $G \rightarrow [\lambda^+]_\theta^{\text{SuS}}$ holds for every commutative cancellative semigroup G of cardinality λ^+ ;
- (3) $G \rightarrow [\lambda^+]_\theta^{\text{SuS}}$ holds for some commutative cancellative semigroup G of cardinality λ^+ .

Proof. Let λ and θ be as above. If λ is regular, then all of the three clauses hold as a consequence of Corollary 3.7 and Theorem 4.2.

Next, as the implication (2) \implies (3) is trivial, and the implication (3) \implies (1) follows immediately from Proposition 4.10 below, let us suppose that λ is a singular cardinal for which $\lambda^+ \nrightarrow [\lambda^+]_\theta^2$ holds.

Then, by [23, Theorem 1], $\text{Pr}_1(\lambda^+, \lambda^+, \theta, \text{cf}(\lambda))$ holds. Then, by Lemma 3.4 and Theorem 4.2, $G \nrightarrow [\lambda^+]_\theta^{\text{SuS}}$ holds for every commutative cancellative semigroup G of cardinality λ^+ . \square

4.2. Finite sums. An immediate corollary to Theorem 4.2 reads as follows.

Corollary 4.6. *Suppose that G is commutative cancellative semigroup of cardinality, say, κ .*

If $S^(\kappa, \theta, \omega)$ holds, then so does $G \nrightarrow [\kappa]_\theta^{\text{FS}_n}$ for all integers $n \geq 2$.*

Our next goal is to derive statements about FS_n from the weaker principle $S(\kappa, \theta)$. We first deal with the case where $n = 2$.

Theorem 4.7. *Suppose that G is commutative cancellative semigroup of cardinality, say, κ .*

*If $S(\kappa, \theta)$ holds, then so does $G \nrightarrow [\kappa]_\theta^{\text{FS}_2}$.*²⁰

Proof. Let $d : [\kappa]^{<\omega} \rightarrow \theta$ be a witness to $S(\kappa, \theta)$. Using Lemma 2.2, embed G into a direct sum $\bigoplus_{\alpha < \kappa} G_\alpha$, with each G_α a countable abelian group. Then, define $c : G \rightarrow \theta$ by stipulating:

$$c(x) := d(\text{supp}(x)).$$

Let $X \in [G]^\kappa$ be arbitrary. Since each $x \in G$ has a finite support, and there are only countably many elements of G with a given support, we have that $\mathcal{X} := \{\text{supp}(x) \mid x \in X\}$ is a subfamily of $[\kappa]^{<\omega}$ of size κ . Let $\delta < \theta$ be arbitrary. As d witness $S(\kappa, \theta)$, we may now pick two distinct $x, y \in X$ such that $d(z) = \delta$ whenever $\text{supp}(x) \triangle \text{supp}(y) \subseteq z \subseteq \text{supp}(x) \cup \text{supp}(y)$. In particular, by Proposition 2.4, we have that $\text{supp}(x + y)$ is such a z , and therefore $c(x + y) = d(\text{supp}(x + y)) = \delta$. \square

We would next like to obtain the corresponding result for FS_n , with $n > 2$. This will, however, not be very hard under the right circumstances, as the following lemma shows. The idea for the proof of this lemma is adapted from [18]. Recall that, given an $n \in \mathbb{N}$, an abelian group G is said to be n -divisible if for every $x \in G$ there exists a $z \in G$ such that $nz = x$ (thus, being divisible is the same as being n -divisible for every $n \in \mathbb{N}$).

Lemma 4.8. *Let $n \in \mathbb{N}$, and let G be an n -divisible abelian group. For every λ, θ , if c is a colouring witnessing $G \nrightarrow [\lambda]_\theta^{\text{FS}_n}$, then c witnesses $G \nrightarrow [\lambda]_\theta^{\text{FS}_{n+1}}$, as well.*

Proof. Suppose that G is an n -divisible abelian group such that $G \nrightarrow [\lambda]_\theta^{\text{FS}_n}$ holds, as witnessed by a colouring $c : G \rightarrow \theta$. To see that it is also the case that for all $X \subseteq G$ with $|X| = \lambda$, $c[\text{FS}_{n+1}(X)] = \theta$, grab an arbitrary $X \subseteq G$ with $|X| = \lambda$. Pick an element $x \in X$, and use n -divisibility to obtain an element $z \in G$ such that $nz = x$. Now, let

$$Y := \{y + z \mid y \in X \setminus \{x\}\}.$$

Then Y is a subset of G of cardinality λ , so that for each colour $\delta < \theta$ we can find n distinct elements $y_1 + z, \dots, y_n + z \in Y$ such that the sum

$$(y_1 + z) + \dots + (y_n + z) = y_1 + \dots + y_n + nz = y_1 + \dots + y_n + x$$

is an element of $\text{FS}_{n+1}(X)$ that receives colour δ . \square

The preceding lemma yields a fairly general result concerning FS_n , where the main piece of information seems to be the cardinality of the commutative cancellative semigroup G , rather than the semigroup itself.

Corollary 4.9. *Suppose that $\theta \leq \kappa$ are cardinals such that $G \nrightarrow [\lambda]_\theta^{\text{FS}_2}$ holds for all commutative cancellative semigroups of cardinality κ .*

Then, for every commutative cancellative semigroup G of cardinality κ , there exists a colouring c that simultaneously witnesses $G \nrightarrow [\lambda]_\theta^{\text{FS}_n}$ for all integers $n \geq 2$.

²⁰Note that when G is the abelian group $([\kappa]^{<\omega}, \triangle)$, then a colouring witnessing $G \nrightarrow [\kappa]_\theta^{\text{FS}_2}$ is *almost* a witness to $S(\kappa, \theta)$.

Proof. Let G be any commutative cancellative semigroup G with $|G| = \kappa$. By Lemma 2.2, we may embed G into a direct sum $G' = \bigoplus_{\alpha < \kappa} G_\alpha$, where each G_α is countable and divisible. This implies that G' is divisible, and $|G'| = \kappa$. Thus, by our hypothesis, we may take a colouring $d : G' \rightarrow \theta$ witnessing $G' \nrightarrow [\lambda]_\theta^{\text{FS}_2}$. Since G' is divisible, we can use Lemma 4.8, to inductively prove, for every integer $n \geq 2$, that d witnesses $G' \nrightarrow [\lambda]_\theta^{\text{FS}_n}$. Therefore $c := d \upharpoonright G$ witnesses the statement $G \nrightarrow [\lambda]_\theta^{\text{FS}_n}$ for all integers $n \geq 2$. \square

We now move to proving no-go propositions. These will be obtained using the following simple proxy:

Proposition 4.10. *If G is a commutative semigroup satisfying $G \nrightarrow [\lambda]_\theta^{\text{FS}_n}$, then $\kappa \nrightarrow [\lambda]_\theta^n$ holds, for $\kappa := |G|$.*

Proof. Fix an injective enumeration $\{x_\alpha \mid \alpha < \kappa\}$ of a commutative semigroup G , along with a colouring $c : G \rightarrow \theta$ witnessing $G \nrightarrow [\lambda]_\theta^{\text{FS}_n}$. Define a colouring $d : [\kappa]^n \rightarrow \theta$ by stipulating:

$$d(\alpha_1, \dots, \alpha_n) = c(x_{\alpha_1} + \dots + x_{\alpha_n}).$$

Now, given $Y \in [\kappa]^\lambda$, we have that $\{x_\alpha \mid \alpha \in Y\}$ is a λ -sized subset of G and hence for every colour $\delta < \theta$, we may find $\alpha_1, \dots, \alpha_n$ in Y such that $c(x_{\alpha_1} + \dots + x_{\alpha_n}) = \delta$, so that $d(\alpha_1, \dots, \alpha_n) = \delta$. \square

Corollary 4.11. *There exists an uncountable cardinal κ such that for every commutative semigroup G of cardinality κ , $G \nrightarrow [\kappa]_\omega^{\text{FS}_n}$ fails for all $n < \omega$.*

In particular, there exists an uncountable abelian group G for which $G \nrightarrow [\omega_1]_\omega^{\text{FS}_n}$ fails for all $n < \omega$.

Proof. The statement holds true for $\kappa := \beth_\omega$, as otherwise, by Proposition 4.10, there exists some $n < \omega$ for which $\beth_\omega \nrightarrow [\beth_\omega]_\omega^n$ holds, contradicting Theorem 54.1 of [5].

In particular, by picking any abelian group G of cardinality \beth_ω , we infer that $G \nrightarrow [\omega_1]_\omega^{\text{FS}_n}$ fails for all $n < \omega$. \square

Corollary 4.12. *Suppose that κ is a weakly compact cardinal.*

Then in the generic extension for adding κ many Cohen reals, for every commutative semigroup G of size continuum, $G \nrightarrow [\mathfrak{c}]_{\omega_1}^{\text{FS}_n}$ fails for every integer $n \geq 2$.

Proof. Let us remind the reader that as κ is weakly compact, κ is strongly inaccessible and satisfies that for every $\theta < \kappa$, every positive integer n , and every colouring $d : [\kappa]^n \rightarrow \theta$, there exists some $H \in [\kappa]^\kappa$ such that $d \upharpoonright [H]^n$ is constant.

Let \mathbb{P} be the notion of forcing for adding κ many Cohen reals. By Proposition 4.10, it suffices to show that in V , we have $\kappa \rightarrow [\kappa]_{\omega_1}^n$ for every integer $n \geq 2$.

Let \dot{c} be a \mathbb{P} -name for an arbitrary colouring $c : [\kappa]^n \rightarrow \omega_1$ in V . Working in V , define a colouring $d : [\kappa]^n \rightarrow [\omega_1]^{\leq \omega}$ by stipulating:

$$d(\alpha_1, \dots, \alpha_n) := \{\delta < \omega_1 \mid \exists p \in \mathbb{P}[p \Vdash \text{"}\dot{c}(\check{\alpha}_1, \dots, \check{\alpha}_n) = \check{\delta}\text{"}]\}.$$

Since \mathbb{P} is *ccc*, the range of d indeed consists of *countable* subsets of ω_1 . As κ is weakly compact, $|[\omega_1]^{\leq \omega}| < \kappa$ and we may pick some $H \in [\kappa]^\kappa$ such that $d \upharpoonright [H]^n$ is a singleton, say, $\{A\}$. Evidently,

$$\Vdash \text{"}\dot{c}[[\check{H}]^{\check{n}}] \subseteq \check{A}\text{"}.$$

As A is countable and \mathbb{P} does not collapse cardinals, \mathbb{P} forces that $\dot{c}[[\check{H}]^{\check{n}}]$ omits at least one colour. \square

5. SOME COROLLARIES CONCERNING THE REAL LINE

Hindman, Leader and Strauss [13, Theorem 3.2] proved that $\mathbb{R} \nrightarrow [\mathfrak{c}]_2^{\text{FS}_n}$ holds for every integer $n \geq 2$. It turns out that it is possible to increase the number of colours from 2 to ω :

Corollary 5.1. *$\mathbb{R} \nrightarrow [\mathfrak{c}]_\omega^{\text{FS}_n}$ holds for every integer $n \geq 2$.*

Proof. As $|\mathbb{R}| = \mathfrak{c} = 2^{\aleph_0} = 2^{\beth_0} = \beth_1$, we infer from Corollary 3.10 that $S(\mathfrak{c}, \omega)$ holds. Now appeal to Theorem 4.2 and Corollary 4.9. \square

On the grounds of ZFC alone, it is impossible to increase the number of colours to ω_1 :

Corollary 5.2. *If there exists a weakly compact cardinal, then there exists a model of ZFC in which $\mathbb{R} \nrightarrow [\mathfrak{c}]_{\omega_1}^{\text{FS}^n}$ fails for every integer $n \geq 2$. Furthermore, in this model, \mathfrak{c} is an inaccessible cardinal which is weakly compact in Gödel's constructible universe.*

Proof. Suppose that κ is a weakly compact cardinal. Work in Gödel's constructible universe, L . Then κ is still a weakly compact cardinal (see [15, Theorem 17.22]), and if \mathbb{P} denotes the notion of forcing for adding κ many Cohen reals, then by Corollary 4.12, the forcing extension $L \models \mathbb{P}$ is a model in which \mathfrak{c} is an inaccessible cardinal that is weakly compact in Gödel's constructible universe, and $\mathbb{R} \nrightarrow [\mathfrak{c}]_{\omega_1}^{\text{FS}^n}$ fails for every integer $n \geq 2$. \square

However, assuming an anti-large cardinal hypothesis, the number of colours may be increased:

Corollary 5.3. *Each of the following imply that $\mathbb{R} \nrightarrow [\mathfrak{c}]_{\mathfrak{c}}^{\text{SuS}}$ holds:*

- (1) $\mathfrak{c} = \mathfrak{b}$ (e.g., Martin's Axiom holds);
- (2) \mathfrak{c} is a successor of a regular cardinal (e.g., CH holds);
- (3) \mathfrak{c} is a successor of a singular cardinal of countable cofinality;
- (4) \mathfrak{c} is a regular cardinal that is not weakly compact in Gödel's constructible universe.

Proof. (1) By Lemma 3.4, Fact 3.5(1), and Theorem 4.2.

(2) By Corollary 4.3(2).

(3) If $\mathfrak{c} = \lambda^+$ and $\text{cf}(\lambda) = \omega$, then $\lambda^{\text{cf}(\lambda)} = \mathfrak{c} = \lambda^+$. Now, appeal to Corollary 4.3(3).

(4) By [33], if κ is a regular uncountable cardinal which is not a weakly compact cardinal in Gödel's constructible universe, then $\square(\kappa)$ holds. Now, appeal to Corollary 4.3(1). \square

By a theorem of Milliken [19, Theorem 9], CH entails $\mathbb{R} \nrightarrow [\mathfrak{c}]_{\omega_1}^{\text{FS}^2}$. We now derive the same conclusion (and even with superscript SuS) from an (again, optimal) anti-large cardinal hypothesis:

Corollary 5.4. *Each of the following imply that $\mathbb{R} \nrightarrow [\mathfrak{c}]_{\omega_1}^{\text{SuS}}$ holds:*

- (1) \mathfrak{c} is a successor cardinal (e.g., CH holds);
- (2) $\text{cf}(\mathfrak{c})$ is a successor of a cardinal of uncountable cofinality;
- (3) $\text{cf}(\mathfrak{c})$ is not weakly compact in Gödel's constructible universe.

Proof. (1) By Corollary 5.3, we may assume that \mathfrak{c} is a successor of a singular cardinal of uncountable cofinality θ . Then, By Fact 3.5(7), Lemma 3.4, and Theorem 4.2, $\mathbb{R} \nrightarrow [\mathfrak{c}]_{\theta}^{\text{SuS}}$ holds. In particular, $\mathbb{R} \nrightarrow [\mathfrak{c}]_{\omega_1}^{\text{SuS}}$ holds.

(2) If $\text{cf}(\mathfrak{c})$ is a successor of a regular cardinal, then by Corollary 3.7, $S^*(\text{cf}(\mathfrak{c}), \text{cf}(\mathfrak{c}), \omega)$ holds. If $\text{cf}(\mathfrak{c})$ is a successor of a singular cardinal of cofinality θ , then, by Fact 3.5(7) and Lemma 3.4, $S^*(\text{cf}(\mathfrak{c}), \theta, \omega)$ holds. Altogether, if $\text{cf}(\mathfrak{c})$ is a successor of a cardinal of uncountable cofinality, $S^*(\text{cf}(\mathfrak{c}), \omega_1, \omega)$ holds. So, by Proposition 3.3, $S^*(\mathfrak{c}, \omega_1, \omega)$ holds. By Theorem 4.2, then, $\mathbb{R} \nrightarrow [\mathfrak{c}]_{\omega_1}^{\text{SuS}}$ holds.

(3) Let $\kappa := \text{cf}(\mathfrak{c})$. By König's lemma, κ is uncountable. By [33], if κ is a regular uncountable cardinal which is not a weakly compact cardinal in Gödel's constructible universe, then $\square(\kappa)$ holds. Thus, by Corollary 4.3(1), $\mathbb{R} \nrightarrow [\mathfrak{c}]_{\kappa}^{\text{SuS}}$ holds. In particular, $\mathbb{R} \nrightarrow [\mathfrak{c}]_{\omega_1}^{\text{SuS}}$ holds. \square

As for FS sets, we have the following optimal results:

Corollary 5.5. *The following are equivalent:*

- $\mathbb{R} \nrightarrow [\mathfrak{c}]_{\mathfrak{c}}^{\text{FS}}$ holds;
- \mathfrak{c} is not a Jónsson cardinal.

Proof. Appeal to Corollary 2.8 with $\lambda = \kappa = \theta = \mathfrak{c}$. \square

Corollary 5.6. *The following are equivalent:*

- $\mathbb{R} \nrightarrow [\omega_1]_{\omega_1}^{\text{FS}}$ holds;
- $(\mathfrak{c}, \omega_1) \rightarrow (\omega_1, \omega)$ fails.

Proof. Appeal to Corollary 2.9 with $\kappa = \mathfrak{c}$ and $\theta = \omega$. \square

In particular, if there exists a Kurepa tree with \mathfrak{c} many branches, then $\mathbb{R} \nrightarrow [\omega_1]_{\omega_1}^{\text{FS}}$ holds.

ACKNOWLEDGEMENT

The first author would like to thank Andreas Blass for many fruitful discussions.
